For Said (1992), the apex of Orientalism in the modern world and in his own biography was Palestine. Understanding the question of Palestine, as constructed in the United States, is instructive for social workers as it illustrates modern day experiences of Orientalism. Social workers, particularly in the United States, have largely been exposed to a single story about Palestine and Palestinians. This story paints an 'us–them' binary with a benign 'us' and 'them' as radical terrorists who undermine the security of Israel and stability of the entire Middle East, thus providing a contemporary instance of Oriental depravity. As social workers find themselves in positions to address the harm done to Palestinians at the micro-, mezzo- and macrolevels, they need to have a greater understanding of the experiences of Palestinians from diverse Palestinian perspectives. Whether engaged in international social work, or microlevel practice with Palestinians living abroad, especially during times of war, social workers must be able to think critically about the ways in which Orientalism informs their theories, practices, and biases. By recognizing, for example, the existence of multiple Palestinian narratives associated with struggle, survival, gender, religion, place, family, and nationality among other issues, social workers, particularly in the United States, become exposed to the diversity of Palestinian experiences and realities, as well as counternarratives that challenge Orientalist and Zionist knowledge about Palestinians.

In his book, *The Question of Palestine*, Said (1992: p. 15) writes that support of Israel or Zionism has "rationalized the denial of present reality in Palestine." The website, *If Americans Knew*, offers a quick overview of some of the hardships and humiliations that comprise the present realities of Palestinians. The Web site makes clear that since the year 2000, there have been at least six Palestinians killed for every Israeli and more than 10 times more children. We do not use these numbers to suggest that any death is tolerable, but rather to show the scale between them. Political imprisonment and detention as well as restrictions on movement and water are common elements of life on the West Bank (*If America Knew*, n.d.).

Although the United Nations has issued 65 separate resolutions indicating human right abuses by Israel regarding the Palestinians (none have been issued against Palestine), Israel is portrayed as the victim in much of the North American public discourse, and efforts to suggest otherwise can carry heavy costs (Carter, 2006b). For example, accusations of being "negative, anti-Semitic, or an apologist for Islam and the Arabs" (Said, 1992: p. 25) are leveled when one deviates from the narrative of Israel as holding a higher moral ground, as evidenced by the vitriolic criticism from some US Democratic leaders and American Jewish organizations when American President

Jimmy Carter (2006) used the word apartheid in his book *Palestine: Peace Not Apartheid* in describing the Palestinian–Israeli conflict (see, for example Northam, 2006). This limited tolerance for a full and critical discourse places Palestinians and Arabs at risk for further marginalization and isolation, in the United States in particular.

Therefore, we know that in addition to marginalization and isolation, individuals of Palestinian descent know our pain, that of our family and community members, and the pain in our country's recent history. For example, Thabet et al. (2002) studied the prevalence of posttraumatic stress disorder (PTSD) among 180 Palestinian children who either experienced bombardment or demolition of their home by the Israeli government when 18 000 Palestinian homes had been demolished. This study found that 54% of the children exposed to this horror experienced clinical levels of PTSD. This prevalence of PTSD affects social workers working with these youth and their families, personally and professionally. For social workers in the West with family and friends living in the occupied territories, the impact can be particularly acute. Such high levels of PTSD also carry implications for social work advocacy concerned with social justice and human rights, and carry implications for the public and mental health effects of occupation and war.

In many parts of the West (especially in the United States), the pain of the Palestinian people is largely unrecognized. For people with Palestinian ties living in the West, the set of feelings regarding the homeland, the fears for loved ones who remain, and the news of traumatic experiences engender grief that is largely unacknowledged and misunderstood by Orientalist societies.

Ken Doka (1989) coined the term 'disenfranchised grief' to write about the pain and difficulty of healing associated with grief that is not supported by society or of which there is stigma associated with the loss. To support Palestinian healing and restore self-determination lost as a result of war and occupation, social workers in the West must attain appropriate information about the effects of Orientalism on Palestinians. They can begin by unpacking the ways by which they have internalized Orientalist constructions of Arabs and Muslims before attempting to help. Given the dominance of Zionist narratives about Palestinians in the United States, accessing this type of information is neither easy nor self-evident. Social workers wanting to educate themselves, prior to working directly with Palestinians in or out of their own countries, may begin by reading some of the references provided in the body of this text, or consider some of the texts listed on *The Faculty Lounge: Conversations about law, culture and academia* (2012). When ready, social workers might engage in antioppressive practice by becoming allies to Palestinians (in or out of their own countries).

The issues affecting Arab and Palestinian youth in particular are potentially important to social workers. Studies speak to the ill effects of racial profiling on youth, but studies informing social workers what it means to go through life profiled as a terrorist, are lacking. Consequently, there is a need for social workers to learn about and research the harm caused by Orientalist stereotypes of Palestinians and Arabs. Beyond educating themselves and gaining the ability to unpack their own Orientalism, social workers can seek out youth groups and organizations that work with young Arabs to become allies that support their self-identified needs. Working with those most affected by Islamophobia and anti-Arab racism, however, is not the only (or even most desirable) way to engage in anti-oppressive practice with these issues. Social workers can also focus their advocacy on changing systems (i.e., racial profiling), institutions (i.e., schools in the West that do not allow young Arab women to wear the hijab), and norms (i.e., constant depictions in the media of Arabs as violent and depraved) that perpetuate these harms.

Critiques

Said's work and his construction of Orientalism is contested. Critiques of Orientalism include that it does just what Said warned about, that is, take a reductionist, essentialized, and global view of the West and the West's description of the Orient. To Said, a critical component of Orientalism is that the West speaks for the Orient. Interestingly, Muslim scholars accused Said, who is Christian, of speaking for Muslims (Varisco, 2007).

The Western Gaze Creating Others in Social Work

Cultural Competence

Through the vantage point of Orientalism, cultural competence in social work takes on additional dimensions and requires further critique. Cultural competence generally refers to developing cultural knowledge and awareness of 'different' cultures, so that one is able to work across these differences.

An important set of critiques found in the cultural competency literature highlights the lack of attention to power associated with specific cultures because culture is typically constructed as neutral (Dominelli, 2002; Pon, 2009). Viewing culture as neutral leaves little room for addressing and critiquing the role that culture plays in perpetuating systems of privilege and oppression. Thus, culture is seen as dichotomized between the poles of normative and 'othered' perspectives. That is, normative is defined as from the West, white, middle class, heterosexual, Christian, male, able bodied, and so on; white and the 'othered,' includes those who identify or are perceived as identifying as people of color; indigenous; noncitizen; gay, lesbian, bisexual, transgender, queer, asexual, intersex; Muslim; poor; disabled; and female, among others. Without a discourse of power associated with culture within cultural competence, an analysis of domination cannot occur (Dominelli, 2002; Park, 2005; Pon, 2009; Sakamoto, 2007).

Rossiter (2007) states, "Domination takes place when the dominator has the power to define the Other from within the dominator's frame of reference and interests" (p. 24). Using Said's (1978) concept of positional superiority, one can argue that by controlling the production of knowledge about culture in the East, the Occident, or West has not only asserted its viewpoint but also enshrined hegemonic power. Consequently, Orientalism is embedded within the notion and practice of cultural competence to the extent that social workers, particularly in the West, study, create knowledge about, and then intervene with 'cultured,' marginalized, oppressed, and

objectified groups. Cultural competence as often practiced in the West can be problematic for a number of reasons including that it encourages social workers to think about and engage in (cultural) differences at the individual and family level, much to the exclusion of macroforces. For example, a cultural competence approach for a Pākehā (Māori term for being of European decent) social worker working with a Māori family focuses on learning about te reo (Māori language) or Tikanga (general behavior guidelines for daily life and interactions in Māori culture) rather than learning about how racism and white supremacy operate in Aotearoa/New Zealand. Without a critical discussion of power, some of the issues associated with the act of being different from the norm – for example, marginalization, silencing, isolation and poverty – are also excluded from the discussion (Dominelli, 2004).

Finally, without a structural analysis of culture and, difference, there is little room to consider the positional privilege associated with social work, that is, the privilege bestowed on certain professions (including social work, mental health, law, medicine, academia) based on their gatekeeping roles and exercise of power. As Margolin (1997) suggests, lack of attention to positional privilege can lead social workers to view themselves as innocent helpers, and not consider the ways in which structural inequalities inform their practices and policies. Dominelli (2002), among others, has specifically urged social workers to focus on how knowledge of 'others' is constructed in and through practice to become proficient practitioners providing locally specific and culturally relevant services rather than learning about reified 'culture' when working with 'others.'

International Social Work

Whether social workers define international social work as 'global awareness' (Asamoah et al., 1997) or as more practice focused, social workers from the West or Global North interested in joining international human rights organizations and nongovernmental organizations (NGOs) operating in the East need to explore Orientalism and its impact on the construction of social problems, service delivery, and policy. Below, we discuss anti–sex trafficking approaches to highlight concrete examples of Orientalism surfacing within and across international social work issues and practices. Anti–sex trafficking approaches offer a vivid example.

Social works' involvement with individuals perceived as sexual slaves/fallen women dates back to the Progressive Era when social workers advocated against what was then called 'white slavery' (Chapkis, 1997; Wahab, 2002). While addressing slavery of any type can be seen as significant for social workers, historians have argued that the fear of 'white slavery' was based not on a large number of documented cases, but rather, societies' fears of cultural contamination due to changing immigration patterns, social anxieties about changing gender roles, sex, class, and race relations at the turn of the twenty-first century (Doezema, 2010; Hobson, 1987). Hobson (1987) points out that the presence of Asian women in brothels drew particular attention as Orientalist notions of Asian women as hypersubmissive fed assumptions that they were imported as sexual slaves. This view removed attention from the race- and class-based exploitation that the women may have experienced upon their arrival in the United States – exploitation that may have led them to the brothel (Hobson, 1987).

Similar Orientalist notions that regard certain Asian, indigenous, and Middle Eastern women as passive, exotic, and victims of their own cultures exist today in social work (Mukherjee and Chowdury, 2012). Evidence shows that sex trafficking exists in Canada and the United States. However, American social work efforts on sex trafficking often emphasize cultural and global 'others.' For example, a piece on human trafficking in the National Association of Social Workers' (Salett, 2006) *Human Rights and International Affairs Practice Update* presents seven examples of what human trafficking and slavery may look like. None of these include North Americans, focusing instead on individuals from India, Thailand, Sudan, Mexico, Moldovia, West Africa (*sic*), and Russia brought into the United States (Salett, 2006).

Orientalist stereotypes have empowered women from the West to define and attempt to solve the issue of sex trafficking for women in the East. The Coalition Against Trafficking in Women is an international NGO with strong local affiliates throughout the world. Its American founder, Kathleen Barry, once stated "In Thailand, religious ideology and patriarchal feudalism reduce the value of women's lives to that of sexual and economic property, which in turn validate prostitution" (1995: p. 182). Instead of recognizing and framing forced prostitution as a consequence of globalization, and complicated socioeconomic, and political forces, many anti–sex trafficking organizations in the West focus on the cultures of the East as the source of oppression for trafficked people. Ditmore and Thukral (2012) provide useful information for service providers who wish to help survivors of sex trafficking without causing additional harm. Their paper outlines the dangers associated with raids to save 'trafficked victims' and they argue for greater law enforcement accountability through human rights and survivor-centered approaches. Social workers can facilitate these approaches by building empowering relationships with immigrant communities and individuals involved in informal economies as well as advocating for greater accountability of labor laws to prevent debt bondage and other violations (Ditmore and Thukral, 2012: p. 147).

Teaching Orientalism in Social Work

A Foundational Critical Theory

Orientalism is taught in some social work curricula to support students' understanding of theory and social work practice. For instance, faculty members (Anaru Eketone and Shayne Walker) at the University of Otago (Dunedin, New Zealand) teach Orientalism to undergraduate social work students to help them understand the ways in which Māori have been constructed, studied, and represented by Pākehā. They also teach Orientalism as a means of supporting the ethical *use of self* in practice. Said's concepts of latent and manifest Orientalism are introduced in a Kaupapa Māori course to unpack the ways in which historical and contemporary constructions of Māori by Pākehā have marginalized Māori culture, tikanga, and te reo through government legislation (Walker, 1990). To gain a deeper understanding of Orientalism as a concept, students

are asked to select a piece of media that depicts Māori or Pacific Islanders in New Zealand. Their task is to critically analyze the selected piece through an Orientalist lens as a means of making 'othering' explicit and tangible. The goal of the assignment is to use the us/them binary of Māori/Pākehā as a method to explore multiple ways in which 'others' are constructed for the benefit of those who are doing the othering, albeit unconsciously at times. In this particular course, faculty members also teach Orientalism as a means of helping students consider their constructions and the gazes of 'others' more generally (not only Māori and Pākehā identities), better to understand privilege and oppression in social work practice across the micro-, mezzo-, and macrolevels.

By understanding Orientalism, students can become more aware of and confront the ways in which objectification, hegemony, and knowledge production are used as policy tools to reduce services and vilify oppressed peoples. Even the term 'welfare queen,' (meaning a woman who cheated the welfare system in such a way that she was able to amass wealth, while being lazy) was utilized to produce major restrictions to welfare policies during the 1990s in countries such as the United States, Canada, and New Zealand. These policy changes focused on controlling the behaviors of poor people rather than addressing poverty through local, regional, national and/or global policy changes, and social and political action. To be an effective policy advocate for individuals who are marginalized, social workers have to see how stereotypes influence the formation of policy and practice.

Conclusion

Orientalism provides a critical theoretical framework through which social workers can explore numerous issues including social workers: participating in systems of inequality, affirming commitments to social justice, and supporting those harmed by stereotypes and oppression, particularly those viewed as coming from the Orient. Conceptually, Orientalism helps social workers make sense of certain types of knowledge construction associated with cultural competence, negative perceptions of Arab and Muslim women, aspects of international social work, Islamophobia, and anti-Arab sentiments, speech, and practices. It can also support social workers in considering certain types of liberatory praxis for developing important counternarratives.

Orthodox Churches

Abstract

The Orthodox Church emerged with the Roman Catholic Church from the apostolic successions in early Christianity, and separated from the Roman tradition sometime between the 11th and 13th Centuries. It is the central Christian denomination in Eastern Europe, Africa, and the Middle East, with many national branches ranging from Russia to Ethiopia. Most were connected for long periods of time to the central Patriarch in Constantinople during the Ottoman Empire. The breakdown of the Ottoman Empire also led to the decentralization of the Orthodox Churches and migration has also created diaspora Orthodox communities.

The term 'Orthodox Church' is the normal term to describe a body that like the Roman Catholic Church, traces its origins to apostolic times. However, it ceased to share in the life of the Roman Catholic Church from the early Middle Ages. It would be misleading to give a single date for the separation of the two traditions. Certainly, 1054 should no longer be treated as the decisive moment of division. More important was the year 1204, when the fourth Crusade sacked the city of Constantinople and thereby demonstrated the 'otherness' of Western as compared to Eastern Christians. The very use of such terms suggests that there were cultural, not merely dogmatic, differences between these areas of the Christian world.

Meanwhile, the Orthodox have spread far beyond their one-time homelands in the 'East.' This was largely the Near East, as defined from a West European point of view. From the ninth century, Central and Eastern Europe were added to this notional 'East.' The modern move of Orthodox communities to other parts of the world tends to make 'Eastern Orthodox' an imprecise if not misleading term.

Some centuries before the separation of the Orthodox and Roman Catholic worlds occurred a different separation in the 'East.' The church council of Chalcedon (451) was the occasion on which a number of church bodies failed to accept the teaching, therefore also the fellowship of the established Orthodox Church in the Byzantine empire. It was (mistakenly) asserted that these were Monophysites. In other words it was presumed that they believed in Christ's single nature as God at the expense of his humanity. The Churches that were supposed to maintain this teaching belonged to the Near and Middle East, as well as to Africa. They are often described as non-Chalcedonian. Less precisely, they are defined as 'Oriental' Orthodox. In the course of the twentieth century, they also have moved far beyond their traditional locations. Unlike the 'Eastern' Orthodox, all of whom follow the Byzantine rite, the 'Oriental' Churches have their separate liturgical traditions.

[†] Deceased.

The 'Eastern' Orthodox at Home

The Former Ottoman Empire

World War I saw the disintegration of the Ottoman empire in which the Orthodox had been always granted a recognized if subordinate role as a people (*millet*).

Under Ottoman rule this *millet* had constituted a clearly segregated society within the Muslim realm. The Orthodox patriarch of Constantinople was treated as its principal administrator or ethnarch. It was possible to escape from the restraints imposed on the *millet* by conversion to Islam. Individuals who chose this way to advancement in the Muslim administration naturally lost the esteem of their former coreligionists. Yet those Orthodox who were executed after subsequent repudiation of Islam came to be venerated as neomartyrs.

The Orthodox Church fostered ethnic or national aspirations in Ottoman times. In effect it was a people's Church. All the more was it ready for new prominence in public life once Ottoman power had come to an end.

Thus the Church of Greece came into its own after the Greek uprising against the Turks (1821). In due course it was proclaimed the established Church of the new Greek kingdom (1852). Likewise the Serbian Church was able to proclaim its independence in 1879. This was in the aftermath of Serbian emergence from the Turkish yoke. Hence the country's Orthodox were eager to assert the unity of Church and state.

The Orthodox of Bulgaria aspired to such unity as well. But the Bulgarian Church claimed its independent status (1870) some years in advance of national independence (1878). Its aspirations were therefore condemned by the patriarchate of Constantinople as untoward, if not heretical (1872–1953). By contrast, the newly established Rumanian Church was to gain the patriarchate's approval in 1885. It had already been recognized by the Rumanian constitution as the country's national ('dominant') Church in 1866. Even after all the assaults of communism the Church could claim the allegiance of 87 percent of the population. The small Albanian Church was not to gain its independence until 1937. Unlike its Balkan partners, it could not claim to represent a majority of the population (no more than 25 percent).

These Orthodox populations could now swim with the tide and use their new opportunities to consolidate their dignity and self-esteem. But in the process they tended to despise their Muslim masters of the recent (even medieval) past. This was to motivate (politically motivated) attempts at ethnic 'cleansing' in Bosnia and Kosovo.

Memories of subjugation could also inspire a revanchist ideology among the Greeks. An aspiration to restore Constantinople as the center of an Orthodox empire animated religious and secular thinkers alike. The latter saw this as their 'Great Idea.' It created no problems until the disarray of the postwar years enticed the Greek authorities to put it into practice. Their ill-fated attempt to restore the one-time Byzantine territories of Asia Minor to the Greeks (1919–22) led to a disaster for the Greek-speaking Orthodox of the region, who were subsequently hounded thence by the victorious armies of Kemal Ataturk. The convention of Lausanne (1923) seemed to legitimize an earlier form of 'ethnic cleansing.' Significantly, this treaty determined that religious criteria should decide how peoples should be moved in the compulsory exchange of populations between Turkey and Greece. Only a small minority of Orthodox Greeks remained in Asia Minor, with the status of their former ethnarch correspondingly diminished. The patriarch of Constantinople was thought to retain merely a symbolic role. Certainly no ethnarch he, since the *ethnos* was displaced.

Only in the Church of Cyprus was the role of ethnarch to retain, even to regain, its former role. Cyprus had been taken from the Turks in 1878 and ceded to the British crown. But the ruling bishop continued to be the leader of the people. This was clearly revealed when Cyprus was seeking independence from the British. The Cypriot archbishop of the day (Makarios) was not only leader in the struggle to achieve this. In the immediate aftermath he was also to gain election as president of the new state (1960–77).

The Church of Cyprus received its independence in 431. The patriarchates of Africa (Alexandria) and the Middle East (Antioch and Jerusalem) are also rooted in the early medieval past.

Despite its once modest numbers, Alexandria claims pastoral responsibility for the whole of Africa. It has consequently acquired a sizeable flock in 60 different countries. This has modified its previously well-established character as a factor of Greek mercantile life.

Greek influence is strong among the leaders of the Jerusalem patriarchate. But it is an influence that is critically assessed by a predominantly Arab flock (perhaps 100 000 strong). By contrast, Antioch (in effect Syria and Lebanon) insists that its Arabic culture is central to its concerns. It is therefore well placed to promote dialogue with its Muslim neighbors.

The Former Russian Empire

Orthodoxy was well entrenched in Russian society by the end of the Middle Ages, and it had few competitors on native soil. But expansion of the Muscovite state from the mid-sixteenth century incorporated peoples with allegiance to other faiths. Muslim peoples were to remain proof against conversion. By contrast, the various pagan peoples of Siberia were often persuaded to join the state Church. Here, as elsewhere, conversion served as a function of colonization. More easily incorporated were the Orthodox of neighboring nations, who joined the Russian empire as the result of one treaty or another. Thus did Ukrainians merge with the Russian Orthodox Church (1686), while the ancient Church of Georgia was accommodated merely as a province (1811). After the church reforms of Peter I (1722), the Russian Orthodox Church was overtly a state church, with the emperor's lay nominee at the head of its subservient synod. It was taken for granted that the population would normally belong to this body. To this end, Orthodoxy was taught in the schools. An annual confession and communion were seen as civic duties. Until an imperial edict of toleration was published in 1905, non-Orthodox religious rivals were restricted in their public life, if not actively restrained; some kind of pluralism might have been envisaged.

But it was not to be. The Bolshevik party, which seized power in 1917, proclaimed separation of Church and state on January 23, 1918. It was soon evident that this involved control, if not suppression of the Church. Most of the Church's many institutions were abolished, and although Stalin's constitution proclaimed 'freedom of worship' (1936), hardly a hundred churches were left open by 1939. Mere membership of the Church involved risk of liberty and life. Among the millions who vanished into concentration camps were almost all the bishops. Meanwhile, anti-religious propaganda was deployed in the formation of *homo sovieticus*. 'Scientific atheism' was taught throughout the schools and universities of the USSR. Membership of the communist party required commitment to the atheist cause.

During World War II a degree of toleration of the Russian Orthodox Church was introduced by Stalin in an attempt to raise national morale (1943) in those parts of the USSR that had escaped German occupation. It was toleration that extended also to the Georgian Church, which had reclaimed independence in 1917. However, such toleration signified no lessening of controls by the party and the state. Rather were these to be extended to Orthodox institutions in the larger Soviet Union of the postwar years.

With equal rigor were controls imposed on Eastern Europe. This meant that the Orthodox church establishment of Rumania and Bulgaria were used to further Soviet interests, while atheism was promoted in society at large. *Mutatis mutandis* the Serbian Church was similarly affected in Tito's Yugoslavia. Yet only in Albania was official atheism to be taken to its logical conclusion: by 1967 religion was prohibited in any of its forms.

By contrast, the Greek Orthodox Church was left free of communist rule at the conclusion of a bitter civil war (1948–49). It was therefore able to continue its existence as established Church. Only one other matched it in this role, the Orthodox Church of Finland. But the two are curiously contrasted. Whereas the Church of Greece represents 98 percent of the population (hence problems of nominal membership), the Orthodox of Finland form hardly more than 1 percent of a predominantly Lutheran population.

The end of communist regimes in Eastern Europe and the former USSR has allowed the local Orthodox Church to reassert its place in secular society. But its potency and numbers are less than might have been expected in the aftermath of large-scale persecution. However, it is no longer barred from education or

from social work, or from public propagation of its faith. Lack of an official ideology has encouraged the substitution of popular (often nationalistic) Orthodoxy by spokesmen of the Church. The Russian form of this nationalism involves an anti-Western stance, with antisemitism one of its ingredients.

The 'Eastern' Orthodox Abroad

Missions

The missionary activities of St Cyril and St Methodios in Moravia (ninth century), and the associated translation of sacred texts from Greek into Slavonic, had legitimized the use of languages other than Hebrew, Greek, and Latin in church life. Later missionaries could therefore work unconstrained in a variety of cultures. Orthodox Christianity was able to bring literacy as well as other social tools to its clients. This was the case with the Siberian and Central Asian missions of the Russian Church. These had their extension to China (1695) and Alaska (1794). In due course there were Orthodox parishes founded in Japan (1868) and Korea (1897). These were modest-sized monocultural outposts of the Orthodox world and thus free of the conflicting loyalties that were later to burden the emigres of Western Europe, Australia, and North America.

The Orthodox Diaspora

Economic pressures and political oppression both led to the migration of Orthodox populations in the course of the twentieth century. Communist rule in Russia and Eastern Europe was among the most potent of the forces that propelled communities into exile. The number of North American immigrants from Russia was swelled by the Russian revolution and civil war of the post-1917 period. Communist rule in Eastern Europe after 1945 also brought Ukrainians, Rumanians, Serbs, Albanians, and Bulgarians to the new world. Meanwhile, Greeks had arrived in considerable numbers after their expulsion from Asia Minor in 1922–23. There were also Palestinians after 1948. In due course Orthodoxy came to be recognized as one of the 'major' religions of the USA.

However, there was never a united church administration. The attempt to form a largely English speaking 'Orthodox Church in America' (1970) did not meet with universal approval. Apart from a Greek archdiocese, which retained its links with the patriarchate of Constantinople, there was a bewildering variety of national jurisdictions, and not infrequently more than one of each. Many immigrants preferred to retain their languages and customs. Even (or especially) in exile their church life was a function of national identity. Similar fragmentation was to be observed elsewhere (Western Europe or Australia, for example).

Diaspora and Mission

However nation-oriented the diaspora, it could still have an effect on its non-Orthodox host environment. The Orthodox may not have sought to proselytize their neighbours. Nevertheless, conversions took place. A common cause might be intermarriage between partners of different faiths. But other less specific causes might also prompt the conversion of individuals or groups.

Some of these have gravitated towards Orthodoxy of their own accord: here is hardly 'mission' in the usual sense of the term. Thus the self-established Orthodox of Uganda and Kenya were assimilated into the patriarchate of Alexandria (1946), and without becoming honorary Greeks in the process. Rather the black Orthodox of Africa (one million strong) have come to outnumber the Greek Orthodox founders of the patriarchate (200 000).

The 'Oriental' Orthodox at Home

However, there were already large numbers of indigenous African Orthodox outside the boundaries of the Alexandrian patriarchate, members of the non-Chalcedonian ('Oriental' Orthodox) Churches of Egypt and Ethiopia.

The Coptic Orthodox Church

The Coptic (= Egyptian) Orthodox Church encompasses much of the non-Arabic part of the population, something like 10 percent of the total. This Church emerged as a distinct entity in the fifth and sixth centuries. But its distinctness was confirmed when the Arabs conquered Egypt in 639–642, since this freed it from Byzantine (= Chalcedonian) control. It has retained its character as the church of its nation. Members of the Coptic Church have experienced constraints from the Muslim establishment. Some of the discrimination exercised by extremists is not far removed from persecution. All the more noteworthy is the vigor of church life among the Copts. In a low-income community this finds its expression in service of the poor.

The Ethiopian Orthodox Church

The Coptic Church supervised the life of the Ethiopian Orthodox Church from the fourth to the twentieth centuries. Not until 1957 was the formal autonomy of the Ethiopian Church proclaimed, and this despite the number of its members (20 million), which far exceeds that of any of its 'Oriental' sister Churches. This accounts for almost half the population. The state encouraged loyalty to the Church when it was an established institution. But much loyalty survived the rigors of a Marxist revolution, not only anti-clerical but anti-religious though it was (1974).

The Syrian Orthodox Church

The 'Oriental' Churches are also represented in the Middle East. Members of the Syrian Orthodox ('Jacobite') Church are distributed between Syria, Lebanon, and Iraq. In terms of culture and membership, this Church was at its strongest in the Middle Ages, but its numbers have declined to little more than 100 000. In the search of anonymity and self-protection (many have fled post-Ottoman Turkey since the 1920s for lack of adequate safeguards) its members tend to emulate their Arab neighbors' way of life.

The Syrian Orthodox Church of South India

However, the Syrian Orthodox gain extra prominence from the existence of their co-religionists in South India, who have been linked with them for much of the period since 1665 through acceptance of a common head, the ('Oriental') Syrian Orthodox patriarch of Antioch. However, the Church of South India, with its 1 500 000 adherents, has its independent history since early Christian times, and its autonomy is fiercely defended by many of its members to this day. As an indigenous church it is well integrated into its milieu (Kerala).

The Armenian Apostolic Church

Armenian home territories are difficult to define. The Armenian republic (formerly a constituent republic of the USSR) is central to them, not least since the spiritual center of all Armenians (Etchmiadzin) is located there. It was founded in 301. However, only a third of the Armenian people reside in that republic. Many find themselves in a diaspora. But others are distributed within the confines of an adjacent administration, the catholicosate of Cilicia (Lebanon) (founded 1441).

Armenia adopted Christianity as its state religion in 301. The Armenian Apostolic Church (its name in later centuries) has remained the Church of the nation since, irrespective of changing frontiers. Armenians in the Ottoman empire gained protection by virtue of their own *millet* (1461). But they could still be subject to pressures and persecution. The last decades of the nineteenth century and the first of the twentieth witnessed massacres of the Armenian population by the Turks that reached their climax in the early years of World War I. Here was a genocide that claimed something like one and a half million lives, a third of the nation. Hence the dispersal of Armenians throughout the world. The persecutions confirmed Armenians in their commitment to their nation, their culture, and their Church.

The 'Oriental' Orthodox Abroad

Missions

The 'Oriental' Orthodox have been little involved in such political imperialism as might have prompted missionary outreach to nations other than their own.

Diaspora

Yet each of the 'Oriental' Churches has branches abroad. Thus Armenians have their communities in North and South America, in Russia, Western Europe, and the Middle East. As many are in the diaspora as in Armenia itself.

Oversharing: The Eclipse of Privacy in the Internet Age

Ben Agger, University of Texas-Arlington, Arlington, TX, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Oversharing refers to disclosing intimate details of one's personal life, especially via electronic means of communication. The causes and consequences of oversharing are examined as a sociology of self-disclosure (or presence) is developed. Of central issue is the fading boundary between private and public life, which is a distinguishing feature of postmodern capitalism. Lacking close friends, people use social media, texting and tweeting, to stay connected. Children and adolescents inhabit a nighttime cyberworld of their own, protesting their overburdening by parents and teachers by disclosing their needy selves. Oversharing might be protest against performativity – the expectation that 'everything counts' and must be graded.

Oversharing (see Gould, 2008; Agger, 2012) is Emily Gould's (2008) term for disclosing too much about oneself. By now, merely half a decade later, oversharing has entered the vocabulary, as both a verb and noun ('that's an overshare…'). It is also called TMI – too much information. It is characteristic of communication in the Internet age (Turkle, 2011), when people are spared social embarrassment by engaging in electronically mediated interaction. Oversharing helps constitute what I call a 'pornographic public sphere', in which intimacy goes public. In this article, I explore social and psychological dimensions of the erosion of boundaries between personal and public lives, a story that will necessarily involve the Internet and cell phones. I am writing on the 10-year anniversary of the inception of Facebook, which began as a Harvard dating site and now boasts a billion users worldwide, with over 30% of them being 35 or over.

Genealogy and Definitions of 'Oversharing'

Oversharing occurs through social media such as Facebook. As of 2014, people may overshare by texting, tweeting, Skyping, and posting porn on the Internet. They may also use Internet dating sites and craigslist to overshare, spin, and engage in self-inflation.

The prefix 'over' implies that people are doing more than sharing. They are sharing too much. This degree of sharing violates Goffman's (1959) distinction between front stage and back stage behavior – the former in role, the latter after one has removed one's costume and makeup and returns to an authentic selfhood. Oversharing violates the perceived boundary between private and public selves, diminishing the realm of privacy, secrecy, and intimacy. While different cultures define the private domain differently, Goffman's insight that all cultures have some sense of privacy is relevant here.

Lasch (1979) wrote of a 'culture of narcissism' in Western countries, characteristic of a stage of capitalism after WWII. His analysis derives from the Frankfurt School, which postulated an 'eclipse' (Horkheimer, 1974) of the self, the autonomous subject capable of mediating between himself and the world. The world saturates and overwhelms us, whittling us down. This makes us needy and self-absorbed, which, clinically, might be described as narcissism. The so-called narcissistic personality disorder involves low self-esteem, which might seem counter-intuitive. I argue that one of the features of alienation in the early twenty-first century is the loss of self-esteem, which leads people to seek solace in largely electronic relationships with others.

Oversharing is a baring of the soul that solicits intimacy and reciprocity. For example: 'I did 10 shots at the bar last night', or 'I slept with a stranger I met there', and even 'I got arrested for DUI'. It involves making the private public to nonintimate 'friends', in Facebook parlance. Of course, what counts as oversharing depends on context. Disclosing intimacies with one's therapist is different from posting them on Facebook, for one's hundreds of 'friends'. Discussing sex with one's partner is different from discussing sex with one's work colleagues. At issue is the context-bound nature of boundaries, which shift and evolve.

One notices a widespread deboundarying in the post-modern stage of capitalism (Agger, 2002; Jameson, 1994). Perhaps the postmodern moment is defined by the suspension of boundaries, especially between the private and the public. People were more discreet in an earlier modernity, and not only because they were Puritanical. There was general agreement that self-disclosure should be boundaried by a sense of propriety, but it was also true that people tended to have a few close friends and intimates with whom to share. The early social theorists, Durkheim, Weber, and Marx, all identified a tendency for modern life to leave people with few strong ties. Durkheim's term anomie and Marx's term alienation were basically synonymous. The decline of face-to-face intimacy in our Internet age corresponds to deboundarying, which leads people to seek intimacy on social-media sites, message board, dating sites, chat rooms, and via text messaging. In other words, the decline of intimate community ('Gemeinschaft') leads to making the private public, dissolving boundaries. Perhaps anomie involves undersharing, where, in a pre-Internet moment, a person lacks intimacy in everyday life and also cannot find it online.

Adults who use Facebook may wonder whether a 1000 Facebook friends are equivalent to a few 'real' friends. That is a tempting question, but not the appropriate one. It already decides in favor of offline versus online relationships as a source of meaningful intimacy. Kids raised in the Internet and Facebook age 'do' social relationships by moving back and

forth between the offline and the online, especially where they can text, which in a way breaches offline and online communication and community by making one's interlocutor present. For the young, texting is more immediate and intimate than voice-to-voice conversation, allowing for greater self-disclosure.

Age and generation are slippery. Divorced parents may seem child-like to their worldly children who watch them return to adolescent dating rituals. In this article, I draw a boundary between people raised before the Internet and people raised since the Internet – pre-digital and digital generations. As with all boundaries, this one blurs as elders learn to negotiate life on the screen and are positioned by it.

Young people and even their parents use FB to arrange movie dates, which they pursue offline. They also use FB to sustain more distant friendships with kids in another county, or with whom they have occasional meetings such as at a quarterly district tennis tournament. Kids use many, and often simultaneous, portals, posting, texting, hanging out. Perhaps the only medium they do not use (for oversharing) is the old-fashioned telephone, which asks of them too much instantaneity and thus exposes them to risk as they cannot stall, edit, mediate, filter. Every parent is exasperated when their kids do not answer their phones, but instead engage in lengthy text exchanges, which they probably conduct while driving or doing their homework.

But Daniel Miller (Miller, 2013) has recently found that 16–18 year olds are leaving Facebook in favor of Twitter, regarding Facebook as a stodgy domain for their parents and other elders. Hill (2009) offers a different perspective on why he left Facebook, largely involving time use and inauthenticity. Miller's work is part of the Global Social Media Impact Study (http://gsmis.org/) which tracks trends in Internet and social media use.

The Needy Self

The needy postmodern self who overshares in order to seek intimacy and reciprocity is characterized by a certain plasticity, or displacement of the ego. Some address personality disorders such as borderline and narcissistic in terms of the loss of self, or of its decentering. One tries to be everything to everyone, manipulating impressions in order to solicit care and love. This is eminently possible using the Internet, which allows one to create one's profile in fanciful and falsifying ways. Everyone has heard stories of dating site profiles that transform the chubby self into svelte and take years off of one's age. This sort of spinning is characteristic of Internet self-assemblage, which also encourages a kind of oversharing as one fills in the broad brush strokes of self-description with the fine details of one's preferences – food, leisure, sex. The Internet calls forth an overindulgence in self-description. Before she bemoaned the privatizing tendencies of the Internet, Turkle (1995) noted that the Internet offered people a 'life on the screen' that allows them to experiment with different identities, something that is important for young people. Indeed, one could define adolescence as the period of growing a self, by trial and error.

Oversharing includes not only these intimate self-descriptions, not to mention self-made amateur pornography, but an opinionated announcement of one's views of the world, especially posted on message boards. As a runner, I have consulted a popular running message board, letsrun.com. This is a board for serious and competitive runners, not for weekend warriors who run a Thanksgiving turkey trot. The letsrun message board is described as 'world famous,' which is perhaps just Internet-era grandiosity.

On the message board, one will find lengthy threads about training theory and the recent performances of elite athletes. The Oregon virtuoso, Galen Rupp, who won silver in the London 2012 Olympic games and recently ran a 3:50 mile indoors, is often discussed, as is the European marathon guru, Canova. But there are other threads on politics, Obama, taxation, sexuality, sexual orientation, and everything under the sun. These posts are sometimes vitriolic, parochial, and often poorly crafted, probably written by young men who run and who also participate in this Age of Opinion. Nevertheless, there is an addictive quality about the message board for serious runners, as we seek mystical wisdom about getting faster, even as we cannot turn away from the train wreck of unsolicited opinion about current events. The boundary between sharing and oversharing seems tenuous here.

Oversharers take license to opine about everything, whether on Facebook or the letsrun message board. An overtly political message board, redstate.com, offers commentary on the Kenyan socialist in the White House as well as on the Newtown tragedy. Crackpotism abounds, which is manifest as a message-board oversharing about all matter of ephemera, from Kim Kardashian to a possible assault-rifle ban. Of course, one's person reasonableness may be another person's lunacy – again the problem of boundaries.

One might distinguish between populism, which involves a certain leveling, and a public sphere in which people produce informed and learned discourse. This is not an argument for academic credentialism, which, as Russell Jacoby (1987) has pointed out, can lead to self-satisfied obscurantism. I applaud his concept of the public intellectual, who writes big books about big issues in accessible prose. Jacoby might agree with me that our Age of Opinion, manifested in untutored oversharing on message boards and in blogs, is inimical to public discourse, and hence democracy. Academization is not an adequate alternative to manic message-board postings which risk regression to the premodern – a kind of flat-earth Babbitism represented by Sarah Palin and other magical thinkers on the right who probably cost Romney the 2012 Presidential election with their bigotry and bad reproductive science.

Gould and I use 'oversharing' with tongue in cheek; whether one discloses too much depends on the standards in use. The term captures the trend toward greater self-disclosure in public, especially in a cybersphere in which people are 'alone together' (Turkle, 2011). What I call a pornographic public culture, arose with (1) the Internet, (2) a larger media culture in which 'reality' becomes entertainment, and (3) sexualization of public discourse and imagery. I hasten to add that pornography is effect, not cause; it is an example of oversharing, of rendering the private public. One can defend filmic sexuality as an overcoming of Puritanism, just as one can defend 'sharing' intimacies with others.

It is not the prurient nature of oversharing that makes it potentially unhealthy. It is the way that oversharing

deboundaries the self by baring all that is at issue. The Frankfurt School's thesis of the eclipse of subjectivity is confirmed by this self-deboundarying, even though they aptly provide no clear guidelines for where boundaries should be drawn. Postmodernists might respond that the Enlightenment concept of a stable self or subject was always a fiction; hence, they prefer to rename the self a 'subject position'. But this endorses alienation and refuses utopia, a good society in which healthy people keep some of themselves hidden while entering public discourse.

Undersharing

Just as one can disclose too much on the first date – sexual preferences, drinking habits, salary – one can disclose too little, which I term undersharing. Undersharing may shade into deception, for example when one does not acknowledge one's marital status or alcoholism. Between undersharing and deception is spinning, when one embellishes one's exercise routine, educational background, love of pets, and sunset walks on the beach. We embellish, spin, deceive, and conceal because people, especially daters, are awash in a mating market that, in the Internet era, can be cruel, as Vitzthum (2007) explains in her *I Love You, Let's Meet*.

Dating sites are a proving ground for my concerns about oversharing. We find self-constructed personal profiles which overshare as well as contextualize, spin, and deceive. Perusing date sites also reveals appropriate sharing, especially by women who, in general, seek relationships whereas Internet-dating men seek sex. There is blurring, especially as people live fast lives and just want to hook up. Divorced parents who work may use dating sites and craigslist to find casual sexual partners, even as we find gender differences in self-presentation, with women likelier than men to tell the truth, but appropriately, without oversharing.

Oversharing may be a relational strategy designed to earn trust and thus advance the relationship. But in telling too much too soon, mystery declines and people move quickly from date to date, relationship to relationship. Vitzthum (2007), using her personal Internet-dating experience, describes coming home from a date and going online in order to search the dating site or sites for a newer, better option. The restlessness in Internet dating mimics and reproduces restlessness in all contemporary life, as people are perpetually unfulfilled in the relational marketplace.

Oversharing is done efficiently as people learn not to waste time on probably fruitless relationships. They are upfront about 'deal breakers' – smoking, children, pets, a certain age range, height and weight, religion. People who engage online seem picky, because they want to move on quickly and because they are accustomed to deception and duplicity. Alienation begets alienation as people are rejected and learn to reject, without allowing relationships to develop serendipitously and in the fullness of time. The reciprocal revelation packed into the first drive-by date at Starbucks, after dating-site picture sharing has been accomplished, is not viewed as oversharing but as the efficient use of time. Here, undersharing would be inefficient, requiring tedious future dates to discover that being a vegan Buddhist is a deal breaker.

Undersharing may respond to structural changes in American society. It may simply be that people have fewer close friends with whom to share, as Brashears (2011) has argued. He tracks the decline of close friends over the past 25 years from three to two. He doubts that Internet friendships, which constitute weak ties in most cases, compensate for the loss of close friends. But others (Hampton et al., 2009) paint a less bleak picture and argue that Internet-based relationships are ample and diverse. Both approaches tell part of the story. I think that the reality is complex because offline and online relationships blur and intermingle, especially for young people, who are adept at moving between the two.

Finally, some people undershare because they are shy, as Cain (2012) has argued, Jung allows for introversion as the anchor of a common personality type (or archetype), as reflected in results on the Myers-Briggs personality test. Many of us bookish types have archetypes that begin with the letter 'I', for introverted. Introversion may be a reasonable response to a world in which the boundary between personal and public is fading; people draw into their shells because they seek to protect their psychic space under assault by electronic invasion.

Boundaries and Personality Disorders

There is something fundamentally different about trading intimacies face to face than online. It is less dehumanizing when staring into the other's eyes, which have a mind and voice of their own. Too little is risked when saying 'I love you' via texting, and risk is essential if the reward of reciprocation is to be gained. Of course, for diminished selves in our fast, postmodern capitalism, little can be ventured emotionally because people are emotionally embattled. Terms such as 'borderline' and 'narcissistic' psychiatrize what is really a social condition: not liking oneself sufficiently. Low self-esteem leads to online intimacy, which involves quick revelation and equally quick rejection or disconnection. Being 'unfriended' or having one's friend request ignored on Facebook both sting.

And so is being ignored, which is the cruelest cut in Internet interaction. Attractive women are overwhelmed with interest by male suitors (or bedmates) on Internet dating sites. There is an erotic economy which governs how many, if any, responses an attractive woman will be able to offer the dozens who message her everyday. This reproduces the pre-Internet dating minuet, where men do the chasing. Women can pick and choose, which gives them a certain upper hand. They learn to be disdainful, and ignored or rejected men lick their wounds, perhaps learning misogyny in the meantime. Why is there an Internet-era erotic economy? Because people work a lot and cannot find time to date, unless they date people from work. And because many are unlucky in love, with divorce and separation littering the landscape. In these contexts, people have less time to 'do' relationships than they did in slower times, when relationships emerged gradually from shared activities and did not move too quickly.

Here, oversharing is an expedient, a quick means of testing the water. But it bears the cost of rejection and being ignored, which only deepens alienation. Whence alienation? From the loss of community, which sociologists have been tracking since

the nineteenth century through our era of suburbs, divorce, workaholism, etc.

Alienation can be traced to Marx's 1843 formulation. The concept has had a Hegelian-Marxist career, becoming reification (Lukacs, 1974) and domination (Frankfurt School). Weber talked about a bureaucratic iron cage, but without Marx's utopian optimism about overcoming it. Being 'alone together', captured in the image of a silent family all texting during dinner, is the latest version of alienation. Oversharing is a desperate attempt to overcome alienation and disconnection, restoring friendship, intimacy, and self-esteem. The Frankfurt School deepened Marx by examining the psychic roots and manifestations of economic alienation. They realized that the self in late capitalism was losing the ability to stand apart from the world and appraise it critically. Instead, people were merely vessels into which commodities and meaning are poured. Before people could engage in the critique of ideology, understanding capitalism and formulating plans to change it, they had to work on themselves by reboundarying their psyches and everyday lives. Retreat from the world would afford the opportunity to read, write, reflect, and imagine utopia.

This is not to indulge in a technological determinism whereby the Internet, cell phones, and the media culture are to be blamed for everything from porn to school shootings. I have argued in *Texting toward Utopia* (2013) that kids are using these prosthetic communication technologies to write their ways out of their misery. Only we elders fail to recognize that this is the most literary of ages, even as youngsters do not turn in their term papers on Shakespeare on time. They text and post up a storm, sharing secret code with other alienated youngsters off the grid of adult expectations and discipline. Seen this way, oversharing has the dialectical potential to undo itself as people seeking intimacy actually find it – love, relationships, affinity groups, social movements. The Internet and texting can be used to organize Occupy Wall Street as well as to post photos of last night's drunken binge at the bar. Adult conceptions of privacy and propriety may need to be rethought at a time when young people 'share' more globally, quickly, and explicitly than we did, especially if young people's prison talk about their oppression by school and parents leads to the mobilization of the young as a new and powerful minority group. Jacobs (2008a,b, 2009) joins me in valuing kids' writing and reading it for tea leaves of critique, resistance, and imagination.

I am, of course, describing the black and white children's movements of the 1960s. The 1962 Port Huron Statement of the Students for a Democratic Society SDS was Xeroxed, stapled, and passed around. It went viral, but only slowly, in bits and pieces. One wonders whether the Port Huron Statement or Malcolm's autobiography, if posted on the Internet, would have gone viral or sunk into the vast Sargasso Sea of the Web. It seems that only viral YouTube videos suggest post-textual manifestos that constitute a cultural politics of resistance and reconstruction. Rock, marijuana, hippies were pre-political, Woodstock making way for marches on Washington and perhaps also to Days of Rage. Yesterday's hippies are today's slackers, kids so turned off by school, teachers, parents, career that they spend their time online, gaming, texting, blogging. This is a kind of Luddite protest against kids' regimentation and more-than-40 hour work week, including homework and college-bound resume building.

Overburdened kids overshare. They are insomniac, too wired to sleep. They claim the night as their own, becoming vampires. They send text messages in a bottle out to sea, hoping for connection and then perhaps community, or at least a date. According to Pew data, the American youngster sends an average of 109 texts a day.

Prison code has always united isolated prisoners. Kids are imprisoned in schools that they hate, and set adrift as latchkey children in families in which everyone has too much to do and is in a separate orbit. Fast families breed virtual children (Agger and Shelton, 2007). Who is to say that sharing is excessive when there is so much pain in the land? School shooters intend suicide as well as others' death. Oversharers produce what I call disturbia – signs and signals of their angst and possibly of their self-destructive intentions. The Columbine shooters, Harris and Klebold, let everyone know: Their friends bought them ammo and videoed them shooting in the woods. One of the fathers found a homemade pipe bomb. The police arrested them for robbing a van. Similarly, Cho at Virginia Tech acted out in his English class, provoking one professor to avoid him, in fear, and another to try to reach him. Gun control would have done little in either case, but love and care would have helped buffer mortal aloneness. Harris and Klebold were not bullied; that is urban legend (Cullen, 2009). They were relatively popular, but it seemed that few adults spent time with them, giving them boundaries and inspiration. The adults are always too busy.

The whole subject of online bullying is an intriguing one. Hinduja and Patchin (2008, 2012) have found that there is relatively little online bullying. Everyone hates a bully, but their findings, like Cullen's, above, about Columbine, suggest that kids use the Internet more for consensus building and community formation than for bullying, although, certainly, gossiping and oversharing abound.

Oversharing, thus, may be a cry for help, especially when kids can use social media to announce their angst. Some of this might be posturing, a way of profiling themselves as cool and diffident. Or it might be real, a reflection of their aloneness and anxiety. School weighs heavily on many kids, as do parental expectations. Adults, especially teachers, are experienced as authoritarian, and oversharing is a reaction, a way of venting and building solidarity.

There may be a blurry boundary between narcissism – 'look at me' – and political mobilization. Cries for help may become calls to arms as kids take back their lives, and their schools. It may be difficult to imagine Facebook, Twitter, and texting as platforms of social change, but they could be, as we see in the Occupy Wall Street and Arab Spring movements. I am hesitant about this because information, communication, and entertainment technologies impose themselves on users and turn self-revelation and compulsive surfing into a nearly inevitable fate. My students check their phones before, during, and after class. They check for messages, mail, alerts. They may be conducting multiple conversations, with complicated threads that never seem to quit. It is difficult for many to be off the grid, especially when one's interlocutors may be employers and parents. Time has expanded into 'iTime', elastic and never-ending (Agger, 2011). People fill it

with their electronic devices, which, unlike radio and television, allow them to interact and write.

This most literary of ages sees billions of words texted and tweeted every day. This should tell us that people have a protean desire to author their own lives, to be writers and thus citizens. The young text and tweet toward utopia, even if they do not spell out their utopias, their ideal worlds, having been focused on fact-based education and not thinking outside the box, let alone thinking about a new world. Lasch's argument about a culture of narcissism is important here. He is noticing that we teach and train people to be inward-looking, focusing on 'self' and not also focusing on others, let alone the whole society. We pour out our hearts in blogs, not in political manifestos, even though the diminished, needy self is a casualty of a postmodern capitalism in which the psyche is invaded and recruited as an insatiable consumer.

So critics like Turkle can easily interpret oversharing as a symptom of narcissism. I could not disagree. However, I think texting and tweeting are dialectical phenomena, perhaps having the potential to become liberating means of Socratic dialogue, public discourse, and political action. Of course, some already use social media to change the world, as the Arab Spring, Occupy Wall Street, and Obama's campaigns indicate. This is a mixed picture: The Internet permits the self to be diverted into consumerism and entertained harmlessly, while the Internet also makes cyberdemocracy possible.

Performativity Provokes Slacking

I have argued that the inward-looking self has become a political factor as well as a casualty of an invasive society that breaks down all boundaries. So what is narcissism? Although the Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association, 2000) is removing narcissistic personality disorder as an official psychiatric condition, everyone understands narcissism to be a personal problem, if not also a social problem. It signifies lack of empathy and perhaps hubris as self becomes central. Clinicians rightly understand that narcissistic and borderline personality disorders involve not self-inflation but low self-esteem. On this view, self-orientedness signals not a Napoleonic impulse, a will to power (although narcissistic leaders can seem that way) but deep self-doubt that is diminished by grandiosity. That does not work and self-esteem remains low. Narcissists who run organizations can quickly seem sociopathological. But there is a narcissist in all of us as most of us are insufficiently satisfied by a world which we experience as harsh and threatening. It is no wonder that kids hide their phones in their hoodies and text each during the interminable school day, when they face performativist expectations and too much boring school work and homework (Kralovec and Buell, 2001).

'Performativity' is the tendency to evaluate and measure all human behaviors. Kids from K through 12, and even beyond, into college, are graded numerous times a day, on quizzes, homework, tests, classroom comportment, hallway and lunchroom behavior. They are then evaluated in their extra-curricular activities, from orchestra and cheerleading to sports. Kids reasonably resist performativism by retreating to a cyberworld in which kids form solidarity by using prison codes in their texting, tweeting, and posting: 'PIR (parent in room)'. People resist performativity, without fully understanding that it is bad for them.

Young and older people have resisted performativism since the Luddite reaction to industrialization starting in the early 1800s. Fordism describes Henry Ford's era of mass production, beginning a century later, made possible by the assembly line. Technology makes for Frederick Taylor's time and motion studies that measure the worker's output and efficiency. Capitalism drives performativity because it wants to maximize profit, which flows from human labor power. The only limit to production is the need for sleep. Sleep deprivation boomerangs as children and their parents awaken bleary-eyed, unable to do on Thursday what they did on Wednesday.

Young people, especially in schooling, are members of a pre-labor force that acquires knowledge, skills, and work habits suited to later marketplace work performance and engages in pre-market work itself, especially homework. This is both preparation for adult work and work itself, which diverts kids from utopia. Whereas Ford-era scientific management evaluated and expedited work performance of adults, today childhood and adolescence have been attenuated as schooling has fallen under sway of performativity, beginning even before elementary school. I think childhood performativity serves capital by preparing a future labor force (Bowles and Gintis' classic 1976 argument) and also diverts kids from non-utilitarian activities in the moment. Adults, themselves alienated, want children to share their pain and hence they pile on the homework and other evaluated activities.

Kids, then, work a more-than-40 hour work (pre-labor) week. They experience insomnia, consume caffeine and speed, learn to hate school, and resent adult authority. Slacking is a response to compulsive performance evaluation and it involves sharing and oversharing among slackers who are, in effect, Luddites, albeit Luddites armed with 3G and 4G cellular technologies.

Oversharing as resistance? Perhaps, inasmuch as saying too much reflects a frenetic desire to connect and seek comfort. How else are we to explain the fascinations of Facebook and message boards, which suck up many hours of attention and diversion? Television is privatizing, whereas sharing is not. Even playing online video games connects, as gamers know. For we elders, that these are not (yet) face-to-face connections matters, but for our progeny avatars stand in for the real thing. And presence is conjured out of reciprocal messaging, composed quickly and in computer quick, deploying slang, acronyms, and emoticons. 'I luv u' is met with 'LOL' and a knowing wink. This is real. Whether it is 'as' real as an in-person exchange depends on one's generation. For the young and Internet adept, 'reality' is not a continuum that comes in less and more. It is the presence of the other, which manifests offline, online, and somewhere in between, perhaps in memory and imagination. Kids who text during school meet after, but do not necessarily discuss what was said. There is a sliding into role that is nearly effortless, much more for the Internet generation than for mine, the boomer generation. Much more can be left unsaid. People who did not grow up with the Internet and texting may find it difficult to cross the boundary beween online and offline relationships, whereas their children

effortlessly relate to each other using multiple portals, including face-to-face interaction. This is why authors of my age risk denigrating online communication as inauthentic, when, for young people, online and offline blur to the point of near identity.

Self-disclosure, then, is a tricky business, requiring us to rethink some standard sociological notions of the stable self, interaction, communication. We need e-sociologies addressing e-life and iTime. We sociological elders are not innocent in these ways. We already know email and cell phones, and many of us text. Many Facebook users are between 18 and 40, although there has been rapid growth of social media participation among people over 40. We rationalize this as a matter of convenience, a way to stay in touch with far-flung family and friends. But all this is imprinting, as we gradually replace face–face and voice-to-voice communication with virtual presence. This asks of us the ability to conjure presence out of absence, taking the role of the other, as symbolic interactionists such as Mead (1962) term it, in order to get on with a new, virtual construction of reality.

That people used to have three close friends, now diminished to two, is bad for intimacy and exacerbates anomie. But the missing friend has been replaced, or augmented, with one's virtual friends who might become 'real' friends and even partners and spouses. E-sociology is sufficiently postmodern that we will not distinguish between the real and the virtual, as I just did. Everything is real, with presence emerging from the screen as well as the gaze and touch. Perhaps that is the twenty-first century predicament: Spilling our gut to a screen, behind which hide many insatiable others.

A Sociology of Presence

A sociology of self-disclosure, then, is a sociology of presence and absence. The Internet and cellular communication call forth these new intellectual approaches. We are virtual selves (Agger, 2004) and we need new frameworks to understand a pixelated, global existence in which downtime nearly disappears. Oversharing might be defined as what you say when you cannot conjure the presence of an other, but only, perhaps, of a generalized other – people like me who might be listening. One cannot imagine blushing, judging, condemning. This is perhaps the difference between writing in a diary when you think your mother would not find and read it, and anticipating that she will read your confession about a first kiss or cutting class. Oversharing occurs when the person does not anticipate that she will be heard and acknowledged; it is a cry for attention. Ignoring and being ignored constitute alienation in the Internet age. This is not to say that telling too much is a viable strategy for being noticed. But people do not always think clearly when they are drunk, awake too late, driving, heartbroken. How many of us have read emails fired off in the heat of the moment? We want to look away.

Presence, then, buffers the self's mortal aloneness, which may be simply to say that we all need friends and intimates. Freud knew this, as did Durkheim. Marx noticed that capitalism pits us against each other, making sharing difficult. Friendship is portable; it can cross the online/offline boundary. One texts one's wife: "Your hair looks good today." Later, one might caress it. Or, "Plz bring home some oranges if you go to the store." Or, even, "here's my latest essay; fyi."

Jurgen Habermas (1989) argues that one of the positive features of early-modern, industrializing Europe was a vibrant public sphere, with coffee houses, newspapers, and libraries. Drawing on images of public life in the Athenian city-state, he applauds a 'public sphere' in which people come together to trade ideas and conduct democracy. Today, the public sphere, rendered digital, invades people's private hours, homes, leisure, even their psyches. Habermas never anticipated oversharing; he linked sharing and democracy. A Habermasian agenda today would include means of protecting the private sphere, in which people turn off, and turn away from, lives on the screen that exert a certain disciplining force (Foucault, 1977).

Abstract

The Pacific Islands, comprising Polynesia, Micronesia, and Melanesia, were explored and settled by humans over a long period beginning in Near Oceania during the late Pleistocene and ending in eastern Remote Oceania *c.* AD 1000–1200. This article reviews recent archaeological, human biological, and linguistic evidence for these complex migrations. Two other major topics of interest to Pacific archaeologists – the evolution of complex societies and human impacts on island ecosystems – are also considered.

The Pacific Islands, also known as Oceania, have been subdivided traditionally into three main geographic regions: Melanesia, Micronesia, and Polynesia. This tripartite division, based largely on crude racial categories, was first proposed by the early-nineteenth-century French explorer Dumont d'Urville. Nonetheless, these geographic categories continue to be used by many anthropologists. Following Green (1991), archaeologists now stress a distinction between *Near Oceania* in the west (comprising New Guinea, the Bismarck Archipelago, and the Solomon Islands) and *Remote Oceania* (which includes all of island Melanesia southeast of the Solomons, along with Polynesia and Micronesia). This latter division recognizes that Near Oceania was colonized by humans in the Pleistocene, whereas the widely dispersed islands of Remote Oceania were not discovered and settled until after *c.* 2000 BC.

Archaeological research in Oceania has a long history, but modern efforts emphasizing stratigraphic excavations did not begin until after World War II (Kirch, 2000), when Edward Gifford of the University of California undertook pioneering excavations in Fiji and New Caledonia, revealing stratified sequences of culture change. Almost all of the main archipelagoes and islands of Oceania have now been subject to archaeological investigations, so that the broad outlines of the region's prehistory are known.

Early Human Settlement of Near Oceania

The oldest known occupation sites in Near Oceania are radiocarbon dated to *c.* 36 000 years ago (the late Pleistocene) on the large island of New Guinea and on New Britain and New Ireland islands in the adjacent Bismarck Archipelago (Allen, 1996). At several times during the Pleistocene, New Guinea was joined to Australia as a single land mass (known as Sahul); it seems probable that human entry into and expansion throughout this vast Australasian region occurred rapidly. Late Pleistocene sites in the Admiralty Islands, New Ireland, and Buka (Solomons), all would have required open ocean transport, indicating the presence of some form of watercraft (possibly rafts, bark boats, or dugouts) (Irwin, 1992).

Early human colonists in Near Oceania were hunters-and-gatherers, who exploited tropical rainforests as well as inshore marine resources. Long-distance communication and exchange are indicated by the movement of obsidian between islands, as well as by the translocation of animal species such as the spotted cuscus (*Phalanger maculatus*). The material culture of these Pleistocene inhabitants of Near Oceania consisted largely of informal flake and core lithics although distinctive 'waisted blades' resembling large axes, as well as tanged core tools, are known from several localities. Although there is no direct evidence of the linguistic affiliation of these early Near Oceanic populations, we can infer that they spoke a variety of proto-languages ancestral to the later Papuan or Non-Austronesian languages of the region.

By the early Holocene period (after 8000 BC), there is archaeobotanical evidence for domestication of tree, root, and tuber crops (such as the *Canarium almond* and various aroids) within Near Oceania. Archaeological evidence suggests that cultivation of swamplands at Kuk in the Highlands of New Guinea commenced as early as 7000 BC (Golson, 1988). These archaeological indications confirm long-held ethnobotanical claims that Near Oceania was one of the several independent centers for the origins of tropical horticulture, including such important crops as taro (*Colocasia esculenta*), sugar cane (*Saccharum officinarum*), and the *Australimusa* bananas.

Austronesian Expansion and Lapita

During the early Holocene, speakers of Papuan or Non-Austronesian languages had expanded as far east as the southeastern Solomon Islands, which marked the eastern limit of human expansion into Oceania. Beginning around 2000 BC, a major expansion or diaspora of people speaking

languages belonging to the Austronesian language family commenced (Blust, 1995). The Austronesian family includes about 1200 extant languages spread from Madagascar to Easter Island. The immediate homeland of the Austronesians has generally been regarded as consisting of the island of Taiwan and, quite likely, adjacent coastal areas of mainland China. The ability of early Austronesians to disperse rapidly has been attributed to their invention of the outrigger sailing canoe (Pawley and Ross, 1993). The Austronesians were horticulturalists who transported root, tuber, and tree crops via their canoes, along with breeding stocks of domestic pigs, dog, and chickens.

The Austronesian diaspora rapidly encompassed the major archipelagoes of island Southeast Asia. One branch of Austronesian speakers expanded along the north coast of New Guinea into the Bismarck Archipelago. This branch is known to linguists as Oceanic, and the Oceanic languages (numbering about 450 modern languages) include most of those spoken throughout the Pacific. The great exception is New Guinea (along with nearby New Britain, New Ireland, and Bougainville), where roughly 750 *Non-Austronesian* languages are spoken. The Non-Austronesian or Papuan languages do not constitute a single unified language family and are highly diverse, reflecting the great antiquity of human settlement in Near Oceania.

Archaeological evidence for the initial Austronesian dispersal into the Pacific comes from both western Micronesia (the Marianas and Palau archipelagoes), and from the Bismarck Archipelago. In western Micronesia, early sites contain red-slipped pottery, some of which is decorated with lime-filled, impressed designs (Carson et al., 2013). These sites, along with radiocarbon-dated sediment cores exhibiting signals of human presence (e.g., high influxes of microscopic charcoal resulting from anthropogenic burning), suggest that humans settled the Marianas and Palau no later than 1500 BC, and possibly as early as 2000 BC.

In the Bismarck Archipelago, the arrival of Austronesian speakers has been correlated with the appearance of a distinctive suite of sites, also containing pottery with lime-infilled decorations, but with motifs made largely by a technique of dentate stamping, in which several kinds of toothed combs were impressed into the damp clay. These sites and the associated artifacts (such as *Tridacna* shell adzes and *Trochus* shell fishhooks, as well as ornaments) represent the earliest known phase of the Lapita cultural complex, dating to *c.* 1500–1300 BC (Gosden et al., 1989; Kirch, 1997, 2000; Spriggs, 1997). Early Lapita sites were frequently hamlets or villages consisting of houses elevated on posts or stilts, situated over tidal reef flats or along shorelines, such as the Talepakemalai site on Eloaua Island in the Mussau group, first occupied around 1500–1300 BC. Excavated plant and animal remains indicate a mixed economy with horticulture and marine exploitation. Substantial quantities of obsidian, chert, pottery, shell artifacts, and other materials were exchanged between Lapita communities (Kirch, 1997).

Correlations among archaeological assemblages, language groups, and human biological populations are often complex, and need not be isomorphic. However, a strong consensus has emerged among scholars in several disciplines that the initial phase of the Lapita cultural complex can be correlated with the *Proto-Oceanic* interstage of the Austronesian language family. Moreover, genetic evidence (such as mitochondrial DNA (mtDNA) and nonrecombining Y-chromosome (NRY) DNA) supports the view that the appearance of Lapita sites reflects a substantial population intrusion into the Bismarck Archipelago, deriving out of island Southeast Asia (Hill and Serjeantson, 1989; Friedlaender, 2007). At the same time, these Proto-Oceanic speakers undoubtedly had considerable interaction (cultural, linguistic, and genetic) with the indigenous Non-Austronesian speaking populations who already occupied the Bismarck region in the mid-Holocene. For this reason the Lapita cultural complex is seen as an outcome of a complex set of cultural interactions summarized by Green's 'Triple-I' model of *intrusion*, *integration*, and *innovation* (Green, 1991).

Human Colonization of Remote Oceania

Beginning *c.*1200 BC, Lapita pottery-makers expanded rapidly beyond the Solomons and – for the first time in human history – into the southwestern archipelagoes of Remote Oceania: Vanuatu, the Loyalty Islands, New Caledonia, Fiji, Tonga, and Samoa. Numerous radiocarbon-dated archaeological sites document that Lapita sites appear in all of these archipelagoes no later than *c.*900 BC. Recent high-precision uranium series dating on coral abraders at the Nukuleka site on Tongatapu pinpoints the arrival of Lapita pottery-makers in this Western Polynesian archipelago at 2838 ± 8 BP (Burley et al., 2012).

We have already noted that the westernmost islands of Micronesia were colonized directly out of island Southeast Asia by Austronesian speakers *c.* 2000–1500 BC. Around 2000 years ago, Oceanic speakers, who made plainware pottery (a late form of Lapita) and who used shell adzes, fishhooks, and other implements, founded settlements on several volcanic islands of central Micronesia (Chuuk, Pohnpei, and Kosrae). The atolls of the Marshall Islands were also colonized at this time.

A distinctive Ancestral Polynesian culture emerged in the Western Polynesian archipelagoes of Tonga and Samoa (along with adjacent Futuna and 'Uvea) out of its Lapita roots during the course of the first millennium BC, through processes of local adaptation and gradual cultural change. Archaeologically, this transition is marked first by changes in the pottery complex, with the loss of the earlier dentate-stamped decoration and development of a distinctive Polynesian Plainware ceramic tradition, as well as by changes in the adz kit, now manufactured from dense basalt. Historical linguists have also traced the development of a distinct Proto-Polynesian language interstage (ancestral to all contemporary Polynesian languages) marked by at least 1300 lexical innovations (Marck, 2000). Applying a 'triangulation approach' that integrates evidence from archaeology, historical linguistics, and comparative ethnology, Kirch and Green (2001) extensively reconstructed this Ancestral Polynesian culture, including aspects of subsistence economy, social organization, and ritual and calendrics.

The final stage in the human settlement of the Pacific Islands began in the first millennium AD, with the Polynesian dispersals eastward out of Western Polynesia (the Tonga and Samoa regions). The timing of Polynesian dispersals into the

central and eastern Pacific (or what is known as Eastern Polynesia) has been a matter of considerable debate among archaeologists (Spriggs and Anderson, 1993; Wilmshurst et al., 2011). Archaeological work, in the 1950s and 1960s, in several Eastern Polynesian islands led to the view that this region had been settled as early as AD 300, but the validity of most of the earlier radiocarbon dates has now been called into question. Recent redating of samples from older excavations combined with new finds in the Marquesas and Mangareva Islands strongly suggests initial human incursion into central Eastern Polynesia between *c*.AD 850 and 1100. The earliest dates for the Hawaiian archipelago are in the range of AD 940–1130 (Athens et al., 2014). The twin large, temperate islands of New Zealand appear to have been the last to have been colonized by Polynesians, around AD 1250 (Anderson, 1989; Davidson, 1984). Critical to the success of this unprecedented diaspora was the double-hulled sailing canoe, capable of carrying 40 to 60 people on voyages lasting one month or longer (Irwin, 1992).

The possibility of Polynesian contact with the Americas has long intrigued scholars. That the Polynesians reached South America and returned is indicated by preserved remains of the sweet potato (*Ipomoea batatas*), a South American domesticate, in several prehistoric Polynesian sites (Hather and Kirch, 1991). Radiocarbon-dated bones of domestic chicken (*Gallus gallus*) from the El Arenal site in Chile have also been claimed to reflect pre-Columbian Polynesian visits to South America (Storey et al., 2007, 2008), although this remains controversial.

Because it was the last sector of Remote Oceania to be settled, and because its populations represent a single radiation or diaspora, Polynesia constitutes a *monophyletic* cultural and linguistic group. Thus, Polynesia has often been regarded as an ideal region for testing models of cultural differentiation from a common ancestor (e.g., Kirch, 1984; Kirch and Green, 2001).

Development of Complex Societies

When the eighteenth-to-nineteenth-century European voyages of discovery inspired by the Enlightenment encountered Pacific Island societies, they frequently found large, dense populations organized into complex, hierarchical sociopolitical formations. With populations often numbering into the tens or hundreds of thousands, such societies had two to three decision-making levels, and hereditary leaders who enjoyed elite privileges and status markers. Anthropologists classify such sociopolitical formations as chiefdoms, and indeed, the Polynesian chiefdoms are often considered the archetypal model (*see* Chiefdoms, Archaeology of).

The origins, development, and elaboration of Pacific Island chiefdoms have been a major topic of archaeological research (e.g., Davidson, 1984; Kirch, 1984; Sand, 1995; Spriggs, 1997). Based on linguistic and archaeological evidence, early Austronesian societies were characterized by some degree of internal ranking (especially between senior and junior branches of a descent line), but were probably heterarchical rather than *hierarchical* in structure. However, heterarchic competition (in such social arenas as marriage and exchange, as well as competition for land) between social groups provided the basis for true hierarchy (and eventually, in the largest societies, class stratification) to emerge.

Archaeologists have identified several factors and processes that were significant in the rise of Oceanic chiefdom societies. Many of these were closely linked, and should not be considered unicausal variables. For example, population growth leading to large, high-density populations can be identified as a necessary, but probably not sufficient, cause underlying sociopolitical complexity (Kirch, 2000; Sand, 1995). The human populations of the volcanic islands typically reached densities of between 100 and 250 persons per km^{-2} prior to European contact, resulting in intense competition for arable land and other resources. Such conditions encouraged centralized, hierarchic control, as well as providing incentives for militaristic aggression.

A second process linked to population growth and to increased hierarchy was intensification of production, including agricultural systems and other forms of production or resource extraction, as well as economic specialization (e.g., in pottery production and trade). On many islands, large-scale irrigation works or dryland field systems were developed during late prehistory. Although population increases may have initially spurred intensification, once in place such intensive food production systems provided a means for surplus extraction by chiefs and other leaders, thus encouraging hierarchy. Often culturally marked as tribute, such surpluses were the economic foundation of an emergent elite, including not only hereditary chiefs, but priests, warriors, craft specialists, and others.

Ideology likewise played a key role in Pacific Island societies, with the elite cadres of the larger and most complex societies actively employing ideological control as a means of legitimation. The origins of Oceanic ritual systems can be traced back to common Austronesian concepts of the sacredness of ancestors; these concepts later became elaborated as cults in which the highest chiefs were seen as directly descended from powerful gods, and hence essential to the continued well-being of the society at large. Archaeologically, the rise of elite-dominated ideological systems is particularly reflected in monumental architecture, of which the most impressive examples are the giant statue-bearing temples of Easter Island (Van Tilburg, 1994), and the site of Nan Madol on Pohnpei (Kirch, 2000). Other forms of monumental architecture, however, are ubiquitous throughout Pacific Islands chiefdoms. Even when monumental architecture is absent, material signs of ideological control can be quite striking, as in the multiple sacrificial interments associated with the burial of Roy Mata, a chief of Vanuatu (Garanger, 1972).

Finally, competition, conflict, and warfare also characterized many of the complex societies of the Pacific, especially following the rise of large and dense populations (*see* Conflict and War, Archaeology of: Behavior and Social Organization). Archaeologically, warfare is marked by a diversity of kinds of fortifications, such as the pallisaded *pa* volcanic cones and headlands of New Zealand, or the ring-ditch fortified villages of Fiji. Another, more gruesome signal of the levels that inter-societal aggression reached on some islands is cannibalism (or para-cannibalistic treatment of enemies,

such as dismembering, roasting, and non-funerary discard of skeletal remains). Although some anthropologists have expressed skepticism regarding European voyagers' accounts of cannibalism in the Pacific, there is now direct archaeological evidence for cannibalistic or para-cannibalistic practices in late prehistory on Easter Island, the Marquesas, New Zealand, Mangaia, and Fiji (Kirch, 2000).

While most of the complex, stratified societies of Oceania would be regarded as chiefdoms, it has recently been argued that the society of Hawai'i, and possibly that of Tonga as well, constituted archaic states prior to European contact (Kirch, 2010; Hommon, 2013). In Hawai'i, a political system with divine kings (*ali'i akua*) who ruled over a society marked by endogamous elite and commoner classes emerged on the large islands of Hawai'i and Maui in the early seventeenth century. This shift from complex chiefdom to archaic state entailed a number of essential changes including the alienation of land from commoner lineages and the imposition of a system of ritualized tribute collection. Similar transformations may have occurred in late pre-contact Tonga, although the Tongan case requires further study.

Human Impacts to Island Ecosystems

The islands of Remote Oceania, due to isolation and related factors, provide model conditions for studying the effects of human colonization and land use on pristine ecosystems. Interdisciplinary research among archaeologists and natural scientists over the past three decades has amplified our understanding of such human–ecosystem interactions (Kirch and Hunt, 1997).

Because of the substantial open-ocean distances isolating them from continents as well as other islands, and the difficulty of dispersal to islands, prior to human arrival, oceanic ecosystems were typically characterized by high species-level endemicity, but lower diversity in higher-level (generic and family) taxa; lowered competition; survival of archaic forms; and *vulnerability* to disturbance from outside agents. Larger vertebrates such as marsupials (wombats and cuscus) and rats, snakes, frogs, and most lizards were restricted primarily to Near Oceania, with only a handful of species declining in numbers eastwards to Fiji and Samoa. The reef and marine resources of Pacific Islands also display a west-to-east decline in species diversity. Throughout most of Remote Oceania, pre-human vertebrate faunas were dominated by birds (including many flightless forms which had evolved in situ from flighted ancestors). Prior to human arrival, these bird populations lacked large vertebrate predators, and presumably also a typical predator avoidance strategy. They must have been extremely easy prey for the first humans to step foot on islands.

When humans first arrived in Remote Oceania, they typically found the islands to be forested, and inhabited by a range of largely endemic species, dominated by birds, along with invertebrates such as landsnails and insects. Oceanic peoples possessed a successful colonization strategy that allowed them to exist on isolated islands by (1) transporting in their sailing canoes stocks of horticultural crop plants, along with domestic pigs, dog, and chickens (rats came along, presumably as 'stowaways'); (2) clearing areas of rainforest for garden land; and (3) intensively exploiting the abundant natural avifaunal and marine resources.

This colonization strategy had several consequences for island ecosystems, all of which are increasingly well documented through both archaeological and paleoenvironmental indicators. Forest clearance on many islands is signaled in changing pollen spectra from sediment cores, with tree taxa rapidly giving away to ferns and grasses; also characteristics are sharp increases in microscopic charcoal influxes, indicating human-induced burning, in most cases probably associated with shifting cultivation. On some islands, forest clearance led to increased erosion rates, along with alluviation of valley bottoms or along coastal plains. The exploitation of natural resources is particularly evident in the zooarchaeological assemblages from early settlement sites, which are characterized by high numbers of land and seabirds, many of them representing now extinct or extirpated species (Steadman, 2006). A dramatic case of avifaunal extinctions on Pacific Islands is that of the *moa*, a group of 13 species of large, flightless birds which became totally extinct in New Zealand during the brief period of Polynesian occupation (Anderson, 1989).

Cumulative effects of human actions on islands led to irreversible changes, such as dramatic declines in biodiversity, and the conversion of natural rainforests to intensively managed, anthropogenic landscapes. The consequences for human populations themselves were undoubtedly mixed. The replacement of natural ecosystems with intensive food production systems enabled the growth of large and dense human populations. At the same time, reduction or depletion of natural resources, coupled with the necessity for intensive land use, encouraged highly complex sociopolitical systems which at times competed fiercely for control of land and the means of production.

Abstract

Acute pain is an adaptive phenomenon that signals impending danger. It is a multidimensional, sensory, and emotional experience and must be differentiated from the physiological process of nociception. When pain becomes chronic, it develops into a disorder in its own right where psychological factors dominate. These include nonassociative (sensitization) and associative (respondent, operant conditioning) learning and memory processes, as well as cognitive and emotional factors. A biobehavioral perspective of chronic pain is based on the view that biological, psychological, and social factors contribute to the experience of chronic pain and they must be addressed in assessment and treatment.

Basic Terms

Pain is an adaptive phenomenon that signals impending danger to the body. Pain can, however, also be maladaptive, for example, in states of chronic pain, and thus can itself become a significant disorder. Epidemiological studies show that 80% of the population experience recurrent pain, with about 19% of the population being significantly disabled by it (Reid et al., 2011). Although pain has for a long time been viewed a purely sensory phenomenon or an epiphenomenon of a medical disorder, this view changed during the last 40 years of the twentieth century. It has been recognized that pain is a psychobiological experience, with emotional aspects being as important as sensory pain characteristics. Thus nociception, the physiological process of a noxious signal being transmitted from the periphery to the brain, has been differentiated from the experience of pain, which encompasses all aspects including psychological, social, and cultural factors. The International Association for the Study of Pain (IASP) definition takes this shift from a biomedical to a biobehavioral or psychobiological perspective into account by characterizing pain as an "unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage" (Merskey and Bogduk, 1994). This definition was prompted by the fact that pain may often be experienced in the absence of identifiable objective pathology. A major change in the traditional view of pain was the gate control theory of pain proposed in Melzack and Wall (1965). More important than its physiological aspects, which have not all been confirmed, was the conceptual model behind it. The gate control theory stated not only that pain could be modulated by both afferent and efferent factors at the level of the spinal cord, but also emphasized that pain has sensory–discriminative, motivational–emotional, and cognitive–evaluative components, and thus it assigns an important role to psychological factors. A core feature of this model is the integration of peripheral stimuli with psychological variables such as mood, attention, or cultural experience in the perception of pain. Thus, the gate control theory has been instrumental in abolishing the dichotomy of psychogenic versus somatogenic pain – psychological and physiological factors always interact in the production of the experience of pain and are not mutually exclusive causes of pain.

Classification of Pain

The common distinction between acute and chronic pain – referring to pain of at least 3–6 months duration and/or pain that exceeds the normal time for healing in the case of an acute injury – is useful, because chronic pain is often maladaptive and needs special attention. While, acute pain such as pain related to medical procedures or childbirth usually leads to anxiety and apprehension, chronic pain tends to be associated with helplessness, depression, and irritability, as well as interference with family function, work, or social interaction (Flor and Turk, 2011). In addition to the large number of workdays that are lost as a consequence of it, chronic pain is the leading cause of invalidity in the age-group of under-50s and causes enormous costs for the health care system (Gatchel et al., 2007).

The IASP classification of pain is organized in five general categories: (1) the bodily system affected, (2) time characteristics, (3) intensity of pain, (4) duration of pain, and (5) its presumed etiology. This classification lacks reliability especially in respect of the last characteristic. In addition, it neglects psychological factors that are only coded with respect to the presence of a psychiatric disorder or within the category 'psychophysiological dysfunction.' The International Classification of Diseases of the World Health Organization as well as the Diagnostic and Statistical Manual of the American Psychiatric Association used to adhere to the distinction between psychogenic–somatogenic or physical–somatoform pain, which must be viewed as obsolete, given the large number of research findings emphasizing the importance of psychological factors in any type of pain, both acute and chronic (Gatchel et al., 2007). Thus, in its more recent versions, both classification systems focus on the symptoms and adverse consequences of chronic pain rather than its putative psychogenic origin and thus favor a biobehavioral or biopsychosocial view.

The biopsychosocial model of pain defines chronic pain as a complex response that can be described on the verbal–subjective, the motor–behavioral, and physiological levels. Pain can be based on nociceptive input, but nociception is not a prerequisite of the experience of pain, which can be an exclusively central phenomenon, but always has physiological antecedents and consequences (Flor and Turk, 2011). The multiaxial classification of pain as proposed by Turk and his

colleagues (cf Turk and Rudy, 1988) categorizes pain patients along both the somatic and the psychosocial dimensions. This classification has yielded three subgroups of patients in the psychosocial domain characterized as adaptive copers, interpersonally distressed, and dysfunctional, with significant differences in the course of the illness and response to treatment. A new multidimensional taxonomy proposed by the American Pain Society (Fillingim et al., 2014) focuses on core diagnostic criteria, common features, common medical comorbidities, neurobiological, psychosocial, and functional consequences, as well as putative neurobiological and psychosocial mechanisms, risk factors, and protective factors.

The Role of Learning in Chronic Pain

Both associative and nonassociative learning processes as well as social learning have been found to be of fundamental significance for the development of chronic pain (Apkarian, 2008; Sandkühler, 2000). The repeated application of painful stimuli usually leads to reduced responsivity, i.e., habituation to the painful stimulation. In many states of chronic pain, sensitization rather than habituation occurs due to changes both at the level of the receptor and the central nervous system. Sensory information accelerates habituation and reduces activation caused by surprise, insecurity, and threat. This mechanism may underlie the effects reported in a large number of studies that support the positive results of preparatory information prior to acutely painful procedures such as surgery or bone marrow aspiration.

The most influential model of psychological factors in chronic pain was Fordyce's assumption that chronic pain can develop and be maintained due to operant conditioning of pain behaviors, i.e., overt expressions of pain. Fordyce (1976) postulated that acute pain behaviors such as limping or moaning may come under the control of external contingencies of reinforcement, and thus develop into a chronic pain problem. Positive reinforcement of pain behaviors (e.g., by attention and the expression of sympathy), negative reinforcement of pain behaviors (e.g., the reduction of pain through the intake of medication or by the cessation of activity) as well as a lack of reinforcement of healthy behaviors could provoke chronicity in the absence of nociceptive input. Thus, pain behaviors, originally elicited by nociceptive input, may, over time, occur in response to environmental contingencies. This model has generated much research, which has not only confirmed the original assumptions made by Fordyce; it has also been shown that in addition to pain behaviors the subjective experience of pain, as well as physiological responses related to pain, are subject to reinforcement learning.

A special role has been assigned to the 'significant others' of chronic pain patients, who have high reinforcement potential. When solicitous, i.e., pain-reinforcing, spouses were present, several studies found that the patients were more pain-sensitive during acute pain tests than when the spouses were absent. The patients with nonsolicitous spouses did not differ whether the spouse was present or absent. These studies suggest that spouses can serve as discriminative stimuli for the display of pain behaviors by chronic pain patients, including their reports of pain intensity. Health care providers may also serve as discriminative cues influencing patients' responses. Solicitous responses by significant others can also lead to increased physiological pain responses in the patients, whereas the focusing on healthy behaviors by significant others can have positive effects on the pain experience (cf Flor and Turk, 2011).

Of equal importance is the operant conditioning related to the intake of pain medication. Patients are often told by their physicians or by well-meaning family members that they should not continue to take analgesic medication unless the pain increases to a point where it becomes intolerable (referred to as *prn* from the Latin, 'take as needed'). When pain medication is taken at that stage, both pharmacological and behavioral factors can contribute to the development of the misuse of medication and, in severe cases, even drug dependence. If analgesic medication is taken only at peak pain levels, the effect of the medication is less potent, and patients cycle between high and low levels of medication that facilitate the development of dependence. In addition, medication intake is negatively reinforcing, since the intake of medication ends an aversive state (pain). Subsequently, the pain-reducing behavior (use of analgesics) increases in frequency. Thus, both pharmacotherapists and behavioral psychologists recommend that analgesic medication should be taken not in a pain-contingent but rather in a time-contingent fashion, adapted to the specific pain level of the patient and to the half-life of the drug.

The negative reinforcement of activity levels is an important process in the development of disability. A specific activity, for example walking, is performed until pain sets in, at which point the activity is interrupted and replaced by rest. Subsequently, the pain will be reduced. The reduction of an aversive state – pain – negatively reinforces the cessation of activity. As was the case with the intake of analgesic medication, the cessation of activity has to be made dependent on the amount of activity achieved – quota-based (e.g., number of stairs climbed, distance walked) – rather than on the amount of pain. Thus, the pain-reinforcing quality of rest is eliminated. This formulation supports the strategy of encouraging patients to perform activities to meet a specific quota, and not until pain is perceived as overwhelming. More recently, the operant formulation of pain has been extended to reward learning, and it has been postulated that pain relief may be processed as rewarding and thus contribute to the maintenance of chronic pain (Becker et al., 2012; Leknes and Tracey, 2008).

The respondent conditioning model postulates that numerous, formerly neutral, cues can be associated with the experience of pain and can – over time – themselves elicit responses that lead to an increased pain response, and can create the experience of pain in the absence of nociceptive input. To illustrate this process, the patient may have learned to associate increases in muscle tension with all kinds of stimuli that were originally associated with nociceptive stimulation. Thus, sitting, walking, bending, or even thoughts about these movements may elicit anticipatory anxiety and an increase in muscle tension. This fear of movement or 'kinesophobia' has been discussed as an important factor in the maintenance and exacerbation of chronic pain (Leeuw et al., 2007). Subsequently, patients may display maladaptive responses to any number of stimuli and reduce the frequency of performance of many activities other than those that initially reduced pain. Thus, although the original association between injury and

pain results in anxiety regarding movement, over time, the anxiety may lead to increased muscle tension and pain even if the nociceptive stimuli are no longer present. In addition, stress situations can increase muscle tension levels and cause sympathetic activation and may, thus, reinforce this process.

Many patients report that an acute pain problem evolved into chronic pain at a time where personal stressors co-occurred with the pain. Stress situations may serve as additional unconditioned stimuli and also as conscious stimulus for muscle tension increases, increased sympathetic activation, and subsequently pain. Nonoccurrence of pain is a powerful reinforcer for reduction of movement. Thus, the original respondent conditioning may be complemented by an operant process, whereby the nociceptive stimuli need no longer be present for the avoidance behavior to occur. People who suffer from acute back pain, regardless of the cause, may adopt specific behaviors (e.g., limping) to avoid pain and they may never obtain 'corrective feedback' because they fail to perform more natural movements. Reduction in physical activity may subsequently result in muscle atrophy and increased disability. In this manner, the physical abnormalities proposed by biomechanical models of pain may actually be secondary to changes in behavior initiated through learning. Chronic pain patients tend to focus their attention on impending pain and subsequently avoid many types of activity, thus fostering the development of disability and depression. The release of endogenous opioids – the body's own analgesic system – may also be influenced by respondent conditioning as well as brain responses related to the experience of pain. Moreover, fear of pain and subsequent avoidance of activity is one of the best predictors of subsequent chronicity (Turk and Wilson, 2010; Wideman et al., 2013).

Response acquisition through the observation of others and modeling is an essential mechanism of learning new patterns of behavior (Martin et al., 2014). Children acquire attitudes about health and health care, and the perception and interpretation of symptoms and physiological processes from their parents and their social environment. They also learn appropriate responses to injury and disease, and thus may be more or less likely to ignore or overrespond to normal bodily sensations they experience. The culturally acquired perception and interpretation of symptoms determines how people deal with illness; the sight of others in pain is an event that captures attention and may have survival value, may help to avoid experiencing more pain, and help to learn what to do about acute pain. Modeling probably plays a part in the phenomenon of 'pain-prone families,' families with a significantly elevated occurrence of pain problems. It was, for example, reported that children show the same pain syndromes as their parents currently have, rather than the pain problems their parents had in their own childhood. The large cultural variations in pain expression are also important. In common clinical practice, the acquisition or extinction of pain-related behavior by means of modeling has received little attention. However, there are occasional indications for the role of modeling in treating pain problems in children in burn units and in the treatment of postoperative pain.

Despite the great deal of data available on the modification of experimentally induced pain behavior by means of modeling in normal (healthy) subjects, there are few experimental results concerning chronic pain patients. Nor are there any longitudinal studies of the development of pain syndromes in 'pain-prone families.' Further investigation is necessary for the evidence of modeling as a factor in the development of chronic pain disorders.

Cognitive Factors and Pain

Cognitive–behavioral models of chronic pain emphasize that the evaluation of the pain experience by the patient greatly determines the amount of pain that is experienced as well as its negative consequences (Flor and Turk, 2011; Skinner et al., 2012). General assumptions that characterize the cognitive–behavioral perspective are: (1) people are active processors of information, not passive reactors; (2) thoughts (e.g., appraisals, expectancies) can elicit or modify mood, affect physiological processes, influence the environment, and serve as impetus for behavior. Conversely, mood, physiology, environmental factors, and behavior can influence thought processes; (3) behavior is reciprocally determined by the person and by environmental factors; (4) people can learn more adaptive ways of thinking, feeling, and behaving; and (5) people are capable and should be involved as active agents in change of maladaptive thoughts, feelings, and behaviors.

From the cognitive–behavioral perspective, people suffering from chronic pain are viewed as having negative expectations about their own ability to control certain motor skills such as performing specific physical activities (e.g., climbing stairs, lifting objects) that are attributed to one overwhelming factor, namely, a chronic pain syndrome. Moreover, chronic pain patients tend to believe that they have a limited ability to exert any control over their pain. Such negative, maladaptive appraisals about their situation and personal efficacy may reinforce the experience of demoralization, inactivity, and overreaction to nociceptive stimulation.

A great deal of research has been directed toward identifying cognitive factors that contribute to pain and disability. These have consistently demonstrated that patients' attitudes, beliefs, and expectancies about their plight, themselves, their coping resources, and the health care system affect their reports of pain, activity, disability, and response to treatment.

Pain, when interpreted as signifying ongoing tissue damage or a progressive disease, seems to produce considerably more suffering and behavioral dysfunction than if it is viewed as being the result of a stable problem that is expected to improve. A number of studies using experimental pain stimuli demonstrated that the belief in personal control can ameliorate the experience of experimentally induced nociception. Moreover, the type of thoughts employed during exposure to painful stimulation has been related to pain tolerance and pain intensity ratings. Catastrophizing thoughts have been associated with lower pain tolerance and higher ratings of pain intensity. In contrast, coping thoughts have been related to higher pain tolerance and lower pain intensity ratings.

Certain beliefs may lead to maladaptive coping, increased suffering, and greater disability. Patients who believe their pain is likely to persist may be passive in their coping efforts and fail to make use of available strategies, even if in their repertoire, to cope with pain. Patients who consider their pain to be an

'unexplainable mystery' may negatively evaluate their own ability to control or decrease pain, and are less likely to rate their coping strategies as effective in controlling and decreasing pain.

Once beliefs and expectancies (cognitive schemata) about a disease are formed, they become stable and very difficult to modify. Patients tend to avoid experiences that could invalidate their beliefs, and they adapt their behavior in accordance with these beliefs, even in situations where the belief is no longer valid (no corrective feedback is received to discredit this belief). For example, feeling muscular pain following activity may be caused by lack of muscle strength and general deconditioning, and not by additional tissue damage.

Self-regulation of pain and its impact depends upon a person's specific ways of dealing with pain, adjusting to pain, and reducing or minimizing pain and distress caused by pain – their coping strategies. Coping is assumed to be manifested by spontaneously employed purposeful and intentional acts, and it can be assessed in terms of overt and covert behaviors. Overt, behavioral coping strategies include rest, medication, and use of relaxation. Covert coping strategies include various means of distracting oneself from pain, reassuring oneself that the pain will diminish, seeking information, and problem solving. Studies have found active coping strategies (efforts to function in spite of pain, or to distract oneself from pain such as activity, or ignoring it) to be associated with adaptive functioning; and passive coping strategies (depending on others for help in pain control and restricted activities) to be related to greater pain and depression. However, beyond this there is no evidence supporting the greater effectiveness of one active coping strategy compared to any other. Specific coping strategies need not always be adaptive or maladaptive. It seems more likely that different strategies will be more effective than others for some people at some times, but not necessarily for all people all of the time, or even the same person at different times and coping should be understood in the context of self-regulation (Van Damme and Kindermans, 2014).

Pain and Emotional Factors

The affective factors associated with pain include many different emotions, but they are primarily negative in quality. Anxiety and depression have received the greatest amount of attention in chronic pain patients; however, anger has also received considerable interest as an important emotion in chronic pain patients. Research suggests that from 40 to 50% of chronic pain patients suffer from depression. There have been extensive and fruitless debates concerning the causal relationship between depression and pain. In the majority of cases, depression appears to be the patients' reaction to their plight. The presence of depression is closely related to the feelings of loss of control and helplessness often associated with pain (Goesling et al., 2013).

Several investigators have also found a close association between fear of pain and dysfunctional coping. In addition, high comorbidity between anxiety disorders and pain seems to be present. Muscular hyperreactivity to stress seems to be closely associated with fear of pain.

Anger has been widely observed in individuals with chronic pain. The internalization of angry feelings seems to be strongly related to measures of pain intensity, perceived interference, and reported frequency of pain behaviors. Anger and hostility are closely associated with pain in persons with spinal cord injuries. Frustrations related to persistence of symptoms, limited information on etiology, and repeated treatment failures along with anger toward employers, the insurance, the health care system, family members, and themselves, also contributed to the general dysphoric mood of these patients. The impact of anger and frustration on exacerbation of pain and treatment acceptance has not received adequate attention. It would be reasonable to expect that the presence of anger may serve as an aggravating factor, associated with increasing autonomic arousal, and having the effect of blocking motivation and acceptance of treatment oriented toward rehabilitation and disability management rather than cure, which are often the only treatments available for chronic pain.

Biobehavioral Perspective

A biobehavioral perspective of chronic pain needs to consider the factors discussed above and their mutual interrelationships in the explanation of chronic pain (Flor and Turk, 2011). The existence of a physiological disposition or diathesis is one important component. This predisposition is related to a reduced threshold for nociceptive stimulation and can be determined by genetic factors or acquired through early learning experiences. It is known that large genetic variations in individual pain sensitivity exist (Mogil, 2012). Furthermore, early stress experience greatly impacts later pain processing (Chapman et al., 2008). A further component of the biobehavioral model is a response stereotype of a particular bodily system, such as exaggerated muscular responses of the lower back muscle to stress and pain that is based both on the diathesis and on aversive experiences present at the time of the development of the response. These aversive stimuli may include personal or work stress or problematic occupational conditions and will lead not only to painful responses, but also to avoidance behaviors and associated maladaptive cognitive and affective processes. The cognitive evaluation of these external or internal stimuli is of great importance in the pain response, as discussed above.

Memory for Pain

An important maintaining factor in this chronicity process is the development of pain memories (Erskine et al., 1990). For example, pain patients have a tendency to remember preferentially negative and pain-related life events and show a deficit in the retrieval of positive memories. The experience of chronic pain also leads to the development of somatosensory pain memories, for example, an expanded representation of the affected body part in the primary somatosensory cortex. This expanded cortical representation is accompanied by increased sensitivity to both painful and nonpainful stimuli, and may be further enhanced by learning processes or attention to painful stimulation. A dramatic example of a learned memory for pain has been found in phantom limb pain patients (Flor et al.,

2006). In upper extremity amputees, the magnitude of the phantom limb pain was found to be proportional to the amount of reorganization in the primary somatosensory cortex, namely, the shift of the cortical mouth representation into the area where the amputated limb was formerly represented. The brain obviously maintains a memory of the former input to the deafferented area. Subsequently, stimulation stemming from areas adjacent to the deafferented zone elicits sensations and pain in the now absent limb. Phantom sensations and cortical reorganization are absent in congenital amputees. The focus of the biobehavioral perspective is thus on the patient and not just on the symptoms or the underlying pathology. This focus also requires that the treatment of the patients be tailored not only to medical factors, but that it incorporates psychosocial variables that may often be predominant in states of chronic pain (*see* Chronic Pain: Models and Treatment Approaches).

Future Perspectives

At the end of the twentieth century, there has been an enormous increase of research in the neurosciences, where the mutual interactions of molecular and genetic as well as neuronal and behavioral variables have begun to be examined. This integration of the psychosocial and biomedical perspective is much needed and will bring substantial advances in our understanding of the phenomenon of pain. A further important development is the finding in neuroscience that the adult brain is enormously plastic, and that learning processes as well as training measures have great impact on these plastic changes. This opens the door for new approaches to treatment (Flor, 2008; Sandkühler and Lee, 2013). It will also aid in delineating and eliminating the factors that lead to resistance to the treatment of chronic pain syndromes.

Paleoethnobotany

Deborah M Pearsall, University of Missouri, Columbia, MO, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Paleoethnobotany is the study of human–plant interrelationships through the archaeological record. Paleoethnobotanists recover, identify, and interpret evidence of past plant use documented through macroremains, pollen, starch, and phytoliths. Not all human activities involving plants result in the deposition and preservation of plant remains in archaeological sites, and natural processes may also introduce plant remains into sites. Paleoethnobotanical data and methods are reviewed, and examples of paleoethnobotanical research presented, including the topics of food and human evolution, the origins of agriculture, uses of food and drink in ritual and feasting, and the case of 'Ötzi,' the Tyrolean Iceman, and his environment.

Paleoethnobotanical Data

Paleoethnobotany, the study of human–plant interrelationships through the archaeological record, provides direct evidence on how past populations met subsistence and other daily needs and contributes to understanding human interactions with their environments, and with each other. Human activities involving plants often leave traces, such as charred seeds, fruit rind fragments, wood charcoal, tuber or root peels, pollen and starch grains, and phytoliths (plant opal silica bodies), which become incorporated into archaeological and geological records. Recovery, identification, and interpretation of such plant remains are the tasks of paleoethnobotanists.

Macroremains

Seeds, fruits, nuts, roots/tubers, and wood recovered from archaeological sites are called macroremains – plant tissues visible to the naked eye or under low magnification (Pearsall, 2000; Hastorf and Popper, 1988). Since such materials deteriorate rapidly under most conditions, survival of macroremains depends on slowing the agents of decay by charring, waterlogging, mineralizing, or desiccation. Incomplete accidental or deliberate burning, resulting in charring of plant tissues, is the most common mode of preservation.

Macroremains are recovered by collection of material *in situ*, through screening, and by a water recovery technique called flotation (Pearsall, 2000). *In situ* recovery preserves the association of macroremains and nonbotanical artifacts, but limits recovery to materials that can be easily seen. Screening allows for more systematic recovery of macroremains larger than the screen mesh, but can damage fragile remains. Water flotation, a technique that uses differences in density of organic and inorganic materials to achieve separation of organic remains from soil, greatly enhances the quantity and size range of macroremains that can be recovered (**Figure 1**). Manual and machine-assisted flotation has become routine in archaeology. Fine-sieving is often substituted for flotation in waterlogged or desiccated deposits, since waterlogged materials are not buoyant, and desiccated remains may be damaged by immersion in water.

Macroremains are identified by comparing unknown archaeological materials to known modern comparative specimens, augmented by published and online sources (Pearsall, 2000). Characteristics important for identification vary by type of remains. For example, seeds are identified by distinctive features of the seed coat, the amount of endosperm and its position in the seed relative to the embryo, and overall size and shape, while wood is identified by its internal structure (vessels and their arrangement, size

Figure 1 Students learning to operate a water flotation system that uses water pressure to separate organic materials from soil matrix.

and arrangement of rays, and abundance and nature of parenchyma). Common challenges to the identification include fragmentation, damage and loss of key characteristics, redundancy of characteristics among related plants, and lack of comparative materials.

Not all human activities involving plants result in the deposition and preservation of macroremains, creating interpretive challenges for paleoethnobotanists. For example, foods consumed or processed away from an occupation site may never become deposited in a garbage midden, while foods eaten raw or prepared as beverages may never be exposed to fire and preserved. This makes interpretation of absence especially difficult. Natural processes, rather than human behavior, may bring plants into what will become archaeological deposits, creating other interpretative challenges. For example, weedy plants may contribute substantial numbers of seeds to midden areas or abandoned dwellings, and wind or water may bring botanical materials into sites. If macroremain preservation is through charring, then material deposited through natural processes, being rarely charred, may have minimal impact on assemblages. Natural processes may also remove macroremains, for example, though erosion of site sediments.

Phytoliths

Phytoliths are produced by the deposition of silica from groundwater into plant tissues. There is a strong genetic component to phytolith formation; orders and families show tendencies for deposition or lack of deposition of silica (e.g., Pearsall, 2000; Piperno, 2006; Runge, 2000; among others). While silicification patterns are redundant in some groups, distinctively shaped phytoliths are formed in many, providing a means of identifying plants at family, genus, or species level. Most phytoliths are the size of silt soil particles (2–250 μm).

Phytoliths are recovered in a specialized laboratory setup for chemical processing from small samples taken for that purpose (Pearsall, 2000; Piperno, 2006). Basically, phytoliths are floated from the matrix using a heavy liquid of specific gravity 2.3 after samples have been treated with a series of chemicals that break down chemical bonds between phytoliths and the matrix. Phytolith extracts are slide mounted and examined under 200–400 power magnification or higher. Phytoliths are identified by comparison of unknowns to phytoliths extracted from identified plant specimens, augmented by online and published sources. Characteristics useful for identification vary widely among plant groups but include three-dimensional morphology, size, surface characteristics, and attachments. Typically, slides are examined until a predetermined count or sum is reached.

Since phytoliths are inorganic, they survive in circumstances under which organic tissues may be lost (Pearsall, 2000; Piperno, 2006). Phytolith representation in archaeological and geological sediments is thus impacted chiefly by phytolith production patterns, i.e., whether or not plants and plant tissues targeted by humans are silica accumulators and produce diagnostic phytoliths. Phytoliths are not indestructible, however. Lightly silicified tissues may break up in soil, and phytoliths may dissolve in highly alkaline environments (pH 9 and higher). Unlike pollen and seeds, phytoliths are not involved in plant reproduction, and so do not have a dispersal mechanism. Phytoliths are released back into the soil by processes that break down plant tissues: organic decay, burning, and digestion. Because phytoliths are released into soil, a large proportion of phytoliths deposited in sediments or soils represent *in situ* deposition. Research indicates, however, that if soil, especially silt and fine sand fractions, moves, phytoliths move. Phytoliths are part of wind-blown dust and soil washed into lakes and swamps, for example. Because both natural processes and human behavior result in deposition of plant remains in archaeological sites, phytoliths become deposited through both these pathways.

Pollen

Pollen is formed in the anthers of seed plants. Most are regular rotation ellipsoids (i.e., symmetrical around an axis) that usually have three concentric layers. The outermost, the exine, contains sporopollenin. This is one of the most resistant natural organic compounds, and is preserved in fossil pollen (Faegri et al., 1989). Although all seed plants produce pollen, pollen abundance and morphology are affected by pollination mechanism. For example, wind-pollinated plants produce many more pollen grains than do animal-pollinated plants, whose pollen has features that ensure that grains stick to the pollinator. Pollen varies in size from 5 to 200 μm.

Like phytoliths, pollen is extracted from small samples in a specialized laboratory. The basic aim is to concentrate pollen and render grains as visible as possible. Concentration is the process of removing everything else from a sample with a series of chemicals, leaving only pollen and spores; rendering the grains visible involves removing clays and other soil components, mounting residue in a suitable medium, and staining (Faegri et al., 1989; Moore et al., 1991). Identification follows the approach already described for phytolith analysis. Features of the exine, as well as grain shape and size, are important for identifying pollen (Kapp, 1969).

The likelihood that pollen will become deposited in archaeological sediments, on artifacts, or in a lake and swamp sediments is affected by pollination mechanism. For example, a major pathway by which pollen is deposited on the landscape is through pollen rain, the mix of pollen transported by air currents (Faegri et al., 1989). Thus, pollen of wind-pollinated plants is highly likely to become deposited in open-air contexts, less likely in closed contexts (e.g., inside structures), while pollen of animal-pollinated plants may only be introduced through the deposition of flowers or fruits with pollen adhering to them. Once pollen is deposited, sporopollenin is tough, but not indestructible. Pollen damage or destruction is reduced in arid or waterlogged soils and in deposits covered by peat formation (acid conditions) because of lower microbial activity (Dimbleby, 1985). Burial of archaeological deposits (by volcanic ash, sand, under-earth mounds, pavements, and within burials) and contact of pollen with artifact surfaces (grinding stones, ceramic vessels, and metal objects) may enhance preservation. In many cases, however, pollen representation in archaeological sediments is a matter of preservation; conditions encountered in many sites are not ideal for pollen preservation (Faegri et al., 1989).

Starch

Starch serves as a plant energy reserve (Gott et al., 2006). It forms in amyloplasts, beginning at a point called the hilum, and grows by successive layers (lamellae), which may remain visible on the granule. Starch is semicrystalline and exhibits strong birefringence, i.e., under polarized light it appears white against the black background, and an extinction cross, a dark cross centered on the hilum, is visible. Starch designed for long-term energy storage is what humans target for food. It tends to be concentrated in seeds and underground storage organs (USOs), but it may also be found in fruits. Storage starch morphology is largely under genetic control, and many plants can be identified by their starch.

Like phytoliths and pollen, starch is extracted in a specialized laboratory from small samples taken for that purpose. The general methodology follows that of phytoliths and pollen, to remove other particles and concentrate the starch (Torrence, 2006). Identification follows the approach already described. Among the characteristics used for identification of starch are granule shape and size, hilum location, extinction cross characteristics, fissure presence and shape, surface and edge characteristics, and whether granules are simple or compound (Gott et al., 2006).

Like phytoliths, starch is not involved in plant reproduction, and does not have a dispersal mechanism. A number of different pathways have been proposed by which starch enters the archaeological record: directly from starchy plant part to soil (e.g., through decay of tubers in an agricultural field); by being consumed or altered by people, then discarded (e.g., decay of tuber peelings in a midden); and by deposition on artifacts used to process starch-rich tissues (Beck and Torrence, 2006). The last named has been the focus of much archaeological research, as well as experiments to investigate how starch is modified by common food preparation techniques. But starch granules have been recovered from a wide range of archaeological contexts, including soils, coprolites, and human dental calculus (Barton and Torrence, 2006). Factors that influence starch survival in archaeological contexts are not yet well understood.

Paleoethnobotany in Archaeology

In the limited space remaining, it is impossible to do justice to the diverse and significant insights into human–plant interrelationships gained through the study of ancient plant remains. A 'taste' will have to serve to illustrate what paleoethnobotany contributes to archaeology.

Human Evolution and the Emergence of Modern Behavior

Understanding early hominin diet is an important component of studying human evolution. Dental calculus traps food particles, including phytoliths and starch grains, and provides direct evidence of diet. Recovery of phytoliths from dental calculus of two 2 million-year-old *Australopithecus sediba* individuals from Malapa, South Africa, revealed consumption of dicotyledonous leaf, fruit, and wood/bark as well as sedge, grass, and palm (Henry et al., 2012). In combination with dental microwear analysis and carbon isotope data, these results revealed consumption of some hard foods and nearly exclusive feeding on a wide variety of C_3 resources, in preference to more widely available C_4 grasses, providing insight into the nature of the environmental relationships of *A. sediba*.

Paleoethnobotany has provided considerable insight into the nature of diet of early *Homo sapiens*. A study of phytoliths from Amud Cave, Israel, suggested that a broadening of diet, including utilization of wild grasses and other seeds, began with Neanderthals (Madella et al., 2002). Cemented sediment patches and intact hearths were sampled, and abundant phytoliths were recovered. Among the plants identified were dicot wood and leaves, grasses, including phytoliths from mature grass seed heads, palm, and fig-tree family (Moraceae), reflecting in large part plant-related human activities, including seed gathering. The evidence indicated broad-spectrum plant foraging during the Middle Paleolithic. Research at the Ohalo II site (23 000 BP), Israel, demonstrated through the study of plant macroremains (Weiss et al., 2004) and starch grains (Piperno et al., 2004) that by the Upper Paleolithic the plant component of human diet in southwest Asia was dominated by an array of wild grasses, and augmented by nuts, olives, fruits, and berries, among other plants. Grass seeds were processed by grinding.

Additional insights into plant-based subsistence strategies in the Middle Paleolithic of southwest Asia come from paleoethnobotanical studies at Kebara cave, Israel. Lev et al. (2005) analyzed charred macroremains from the site. Charred remains were found primarily near hearths. The vast majority of the 3956 identified seeds were legumes (Papilionaceae), but a wide variety of seeds were found in small numbers, including grass, goosefoot, safflower, seeds of several plants producing USOs, including wild radish and nut grass, and several species known for medicinal uses. Acorn and pistachio nut fragments were also recovered. The presence of charring suggested cooking of vegetal foods. Albert et al. (2012) studied phytoliths and thin sections taken from hearths and combustion features at Kebara. The generally high number of phytoliths present in samples suggested that plants were abundant in the cave. Those most directly related to anthropogenic deposition were from wood used as fuel for fires and grasses used to help start fires (or adhering to wood). Abundance of phytoliths from grasses and seed coats of the Boraginaceae in samples near the entrance of the cave was likely due to their growth at the entrance.

Study of microfossils in dental calculus of Neanderthal individuals provides further support for breadth of Neanderthal diet (Henry et al., 2011). Henry studied dental calculus from three teeth from Shanidar III, Iraq, and two each from Spy I and II, Belgium. Numerous starch grains were recovered and some phytoliths. In the warm Mediterranean region, Neanderthal individuals consumed grass seeds of the Triticeae tribe, including some that appeared to have been cooked, legume seeds, an unknown USO, and date palm. In cold northwestern Europe, consumption included an unknown USO and grass seeds (Andropogoneae tribe). These results showed that two major hominin dietary adaptations, cooking and incorporation of a diversity of relatively costly plant foods, had taken place by the Middle Paleolithic.

Beyond diet, paleoethnobotany contributes to understanding the emergence of other modern behaviors in the Middle Paleolithic. For example, research at Tor Faraj, a rock shelter site in Jordan, provided insight concerning the extent to which Neanderthal behavior resembled that of modern humans (Henry, 2003). Rosen (2003) conducted a study of plant microfossils, focused on reconstructing local vegetation, paleoclimate, and pattern of plant use by the shelter's inhabitants. Samples were taken horizontally across the living floor. Abundant phytoliths were recovered, as well as some spores, starch grains, and calcium oxalate crystals. Among the plants identified were pooid (festucoid) grasses, reed, sedge, date palm, and abundant phytoliths from trees or shrubs, suggesting that much moister conditions existed in the area at the time of site occupation than at present. Date palm fruits and/or leaves were likely used. Several kinds of starch grains were found, likely indicative of nuts, such as pistachio, roots, and tubers brought into the shelter. The distribution of microbotanical remains across the living floor indicated that grasses were spread on the floor near the back wall and in between the hearths, perhaps indicating prepared sleeping areas. Phytoliths from grass seeds and palm were concentrated near a hearth, suggesting a food preparation area, while high concentrations of dicot phytoliths beyond the drip line of the shelter suggested a brush windbreak. The microbotanical results contributed significantly to the overall finding that the inhabitants organized their activities essentially along the lines of modern hunter-gatherers (Henry, 2003).

A phytolith study conducted at Esquilleu Cave, Spain, by Cabanes et al. (2010) also documented the use of grass as bedding during the Late Mousterian. Most of the phytoliths recovered from samples were of grasses (leaf and inflorescence) but several hearth samples had abundant wood and bark phytoliths. Phytolith dissolution occurred in some areas. In areas of good preservation, accumulation was related to use of grass in bedding (in repetitive layers) and wood/bark for combustion. Interpretation of such layers of phytoliths as bedding is supported by an experimental study by Miller and Sievers (2012). They studied the micromorphological signatures of burned bedding, in order to gain insight into how laminated layers of carbonized material and phytoliths were produced, in this case, at the Sibudu site, South Africa. The experiment revealed that large volumes of vegetal material could have produced thin archaeological deposits of burnt bedding, and that if carbonized material was present, burning was most likely deliberate.

Origins of Food Production

Paleoethnobotany is at the heart of research into the origins of food production. The American tropics provide an example that illustrates the power of combining multiple indicators of plant use to document early agriculture. The early history of American plant domestication begins in lower Central America and northwestern South America, and is known in large part from phytolith, starch grain, and pollen evidence. Pollen and phytolith sequences from lakes indicated that populations began modifying landscapes in the early Holocene. Burning of forests and small-scale land clearance was documented then at Lake La Yeguada in Panama, for example (Piperno and Pearsall, 1998). Phytoliths also fill in the record at early sites with poor preservation of macroremains. For example, arrowroot, llerén (two root/tuber crops), gourd, squash, and maize (corn), all identified by phytoliths, were found at two early sites in Panama, Cueva de los Vampiros and Aguadulce.

Research at Xihuatoxtla shelter in the Central Balsas River valley, west Mexico, has now documented early maize in the dry tropical forest setting of its wild ancestor (Piperno et al., 2009). Maize phytoliths were recovered from site sediments, and maize starch and phytoliths from grinding stones, dating to 6700 BC. The spread of maize through the lowland tropics from its area of origin has been documented in part by pollen and phytoliths in sediment cores. Evidence for maize was found, for example, at 5100–5000 BC in a sediment core on the Gulf coast, and maize pollen and/or phytoliths documented the crop in south Pacific coastal Mexico, Pacific coastal Guatemala, northern Belize, and Honduras by 3500 BC (Piperno and Pearsall, 1998). Maize was carried south through the tropical lowlands prior to this time, however, as it is documented earlier in Panama, Colombia, and Ecuador. Perhaps the best known maize remains come from two caves, Coxcatlán and Guilá Naquitz, each located in the semiarid highlands of central Mexico. Maize macroremains were well preserved in these dry sites, but when directly dated, not all were as ancient as expected from site stratigraphy. Maize has been direct-dated to 3600 BC at Coxcatlán and 4250 BC at Guilá Naquitz (Long et al., 1990; Piperno and Flannery, 2001).

The emergence of agriculture in the dry tropical forests of southwest coastal Ecuador has also been documented largely through microfossil data (Piperno and Pearsall, 1998). Squash phytoliths were recovered from terminal Pleistocene and early Holocene strata at preceramic Vegas sites; other Vegas crops included gourd and llerén, and eventually maize. Maize, identified by phytoliths and starch grains, continued to be grown at Real Alto and Loma Alta, two later, Valdivia tradition farming villages, along with cotton and jack bean (preserved as macroremains), achira, manioc, chili pepper, llerén, and arrowroot (identified by phytoliths and/or starch grains) (Chandler-Ezell et al., 2006; Zarillo et al., 2008). Agriculture in coastal Ecuador remained broad-based for many millennia, incorporating wild/managed tree fruits as well as annual crops (Pearsall, 2004).

Research at early preceramic sites in the Ñanchoc valley, located in the lower western slopes of the Andes in northern Peru, has provided the first detailed look at early farming communities in the Andes. Recovery of macroremains from sealed house floors and hearths has documented cultivation of squash, peanut, quinoa (all by 7500 BP or earlier), and cotton (by 5500 BP) (Dillehay et al., 2007). Manioc and other unidentified tubers and fruits were also recovered. The early presence west of the Andes of peanut and manioc, originating in eastern South America, and quinoa, from the southern highlands, has documented the extent of networks of communication and exchange among early agriculturalists. Study of starch recovered from the dental calculus of 39 teeth from the same contexts as the dated macroremains led to the identification of starch from bean and pacae seeds (tree fruit), squash flesh, and peanut (Piperno and Dillehay,

2008). Starch from these four taxa was commonly recovered; rarer types identified included possible manioc and tree fruits. Irrigation technology, vital to the later development and expansion of agriculture in desert coast Peru, was also documented early in the Ñanchoc valley, in the form of small-scale gravity canals (Dillehay et al., 2005). Paleoethnobotanical and archaeological evidences from this small valley combine to indicate how early effective farming emerged in western Peru, and took on a regional identity (Dillehay, 2011).

The Iceman and His Environment

In September 1991, a well-preserved corpse of a man was discovered frozen in the Alps at 3214 m elevation. Eventually dated to more than 5000 years ago, studies of 'Ötzi,' the Tyrolean Iceman, and his tools and clothing have provided a snapshot of life in the Alps during the Neolithic. Detailed paleoethnobotanical studies played a central role in understanding Ötzi's life and death and his natural environment. For example, study of pollen sequences from bogs and peat deposits demonstrated that the alpine grasslands of the region were used as pastures since the beginning of the Neolithic (Bortenschlager, 2000). Forests were also cleared to increase pasturage. Ötzi was likely involved in an early form of transhumance, moving his flocks seasonally to higher elevation pastures. Wooden objects found with Ötzi were identified through dendrological analysis. Ötzi's bow and the handle of his ax, for example, were made of yew, while arrow shafts were made of wayfaring tree (Oeggl and Schoch, 2000). His pack frame was made of hazel and larch. A birch-bark container was filled with maple leaves and charcoal fragments, and probably served as a storage container for cold embers. The majority of wood species belonged to the montane region, and technological analysis suggested that Ötzi selected species based on the requirements of each object.

Study by Oeggl et al. (2007) of a sequence of gut samples revealed what Ötzi ate during the last hours of his life, and what kinds of environments he traveled through. Pollen, plant macroremains, whipworm eggs, and muscle fibers were recovered. Pollen can become incorporated into food residue in the gut in a variety of ways, for example, through food consumption, drinking water, and breathing. Only frequently occurring pollen was interpreted as associated with food consumption. Ötzi's last meals included meat, wheat, bracken, chenopod, and plants in the primrose and legume families. At least three different meals were identified. Abundant charcoal particles suggested that Ötzi's meals were prepared over an open fire. Background pollen from the gut series indicated that Ötzi traveled from the subalpine region down to the valley bottom, and then back up to the alpine region, where he died from an arrow wound.

Study of macroremains recovered from the location of Ötzi's discovery, a rocky hollow, provide further insights into the Iceman, his life, and his environment (Heiss and Oeggl, 2009). Materials studied included Ötzi's clothing and equipment, some of which was made of plant material, such as a grass cape/mat and grass shoe insulating material. Plant remains were also recovered from Ötzi's clothing and equipment and from wet-sieving or floating sediments from the bottom of the hollow. In all, over 40 000 plant macroremains have been studied, from at least 66 species, representing environments from the valley bottom to the snow line. However, only Ötzi's equipment, clothing, and the cultivated plants found in association with him, hulled barley, einkorn, millet, opium poppy, and flax, can be unambiguously considered the result of human rather than natural deposition through long-distance transport.

Ritual and Feasting

Beyond their roles in diet and economy, foods (and drinks) play important roles in social relationships, both public and private. In the Andes, for example, maize beer *(chicha)* is an important part of cultural identity, and plays a central role in ceremonies. Documenting when this role emerged was one goal of paleoethnobotanical research at Formative sites on the Taraco Peninsula, Bolivia (Logan et al., 2012). Phytolith and starch grain analyses were used to investigate maize processing and its consumption in both ceremonial and domestic contexts. Charred maize remains were lacking at sites, and no maize microfossils were recovered from cooking pot residues. The only evidence for maize processing came from phytolith or starch residues on grinding stones from a ceremonial space, on teeth of a sacrificed individual, and in other ceremonial contexts, such as burials and sunken courts. The evidence supported a ceremonial role for maize, probably in liquid rather than cooked form.

Study of macroremains, starch, and phytoliths from a buried ceremonial room at the Buena Vista site provides insights into ritual feasting during the preceramic period in coastal Peru (Duncan et al., 2009). The ceremonial room, a small temple of the Kotosh tradition, was intentionally buried, and food remains were part of the ritual entombment. Macroremains recovered from the room, well preserved by the desert conditions of the coast, were dominated by nonedible parts of food plants and broken gourd and squash serving vessels. These were not food offerings, but the refuse from feasting associated with the ritual burial of the temple (Duncan et al., 2009). Ritual entombment of buildings has been documented in the region, but not the association of feasting with temple burial. Study of starch residues from the gourd and squash artifacts recovered starch from manioc, potato, chili pepper, arrowroot, and algaroba. Starch and phytoliths recovered from artifacts and sediments led to identification of foods (and drinks) not present as macroremains.

There is a long tradition of studying plant food offerings from cremation cemeteries of the Iron Age and Roman Empire (Rottoli and Castiglioni, 2011). Since all offerings were subject to burning during the funerary rites, chances of preservation are high, and preservation is less selective, in comparison to macroremains preservation at contemporary habitation sites, for example. In their review of plant food offerings from Roman cremation sites in northern Italy, Rottoli and Castiglioni (2011) found that while cereals, legumes, cultivated and gathered fruits, vegetables, and prepared foods, such as bread, were often all present, fruit remains were especially common. This abundance contrasted markedly to abundance of fruits preserved at habitation sites. Presence of

grapes and hazelnuts in Roman cremations indicated continuity of local, Iron Age, traditions, to which offerings of other fruits, such as fig, date palm, olive, and pine nut became increasingly common. Another legacy of more ancient customs was indicated by isolated offerings of wild fruits such as acorn, strawberry, and rose. No evidence of consumption of foods was found, i.e., no remains of meals or preparation waste. Fruits, seeds, and prepared foods were offered in their entirety. Studies of plant food offerings provide insights into the Romanization of new territories and document the growth of trade, including new and exotic fruits, in Roman times.

Abstract

A panel survey makes similar measurements on the same units (e.g., individuals, firms) at different points in time. Analytic advantages of panel as opposed to cross-sectional survey data include the ability to measure components of individual change, the ability to collect a wider range of data on each sampled element, and the provision of high-quality intergenerational data and measurements of the frequency, timing, and duration of events. Problems with panel but not cross-sectional surveys are panel nonresponse and, in some cases, panel conditioning, where responses in a given interviewing round may be conditioned by participation in prior rounds of interviews. Examples of panel data analysis include poverty dynamics, the intergenerational transmission of economic status, unemployment and labor turnover, and antecedents of life events.

A panel survey makes similar measurements on the same sample units (e.g., individuals, firms) at different points in time (Duncan and Kalton, 1987). Panel surveys can be distinguished from: (1) cross-sectional surveys, which take measurements on sample units from a population of interest at a single point in time; and (2) repeated surveys, such as the US General Social Survey (Davis and Smith, 1994), in which similar measurements are made on samples from an equivalent population (e.g., defined by identical geographical boundaries or birth cohorts) at different points of time, but without attempting to ensure that any elements are included in more than one round of data collection.

A widely used alternative term for panel survey is longitudinal survey. However, it is useful to use 'longitudinal' only in the context of longitudinal *data*; such data may be collected by a panel survey, but they could also come from retrospective reports in a cross-sectional survey.

Most panel surveys follow their sample elements for the duration of the survey. Other panel designs include a rotating panel survey, in which sample elements have a restricted panel life; as they leave the panel, new elements are added. Examples of this are the monthly US Current Population Survey (US Bureau of Labor Statistics, 2000a) and the Canadian Labour Force Survey (Statistics Canada, 2000), in which the sample at each month is composed of a number of rotation groups, each of which is a self-contained sample from the population of interest. One rotation group drops out and one rotation group enters each month. A split panel survey is a combination of a panel and a repeated survey (Kish, 1986).

Panel surveys can differ markedly in the interval between rounds of data collection and the overall length of the survey. On the one hand, a consumer panel in market research may involve weekly contacts with respondents to collect their diary records of purchases. On the other hand, there are long-term panel surveys that may collect data only annually or even less frequently, and these surveys may continue for many years. Examples are the Panel Study of Income Dynamics (PSID), which had been collecting data on US households annually (biannually since 1997) since 1968 (Hill, 1992), and the British National Child Development Study, which started in 1958 and has collected data on the sample persons on five occasions in the 33 years to 1991 (Institute of Education, 2000).

Some panel surveys are concerned with population subgroups that have experienced the same event during the same time period, such as attending eighth grade in a given year, having been born in a particular week, or having been married during the same period. Since these sample universes are defined as cohorts, such studies are often called cohort studies. Examples include the various cohorts defined by age and sex in the US National Longitudinal Surveys (US Bureau of Labor Statistics, 2000b). A limitation of cohort studies is that their results relate formally only to the particular cohorts from which the sample was selected. An extension of the approach is the multiple cohort design, in which several cohorts are followed in similar panel surveys. Thus, the National Longitudinal Surveys have begun three youth cohort panel surveys, in 1968 (males) and 1968 (females), 1979, and 1997, while the Monitoring the Future studies have selected samples of US high school seniors each year, and follow each sample in a panel survey (Monitoring the Future, 2000).

Despite their lack of formal population representation, still other panel surveys are valuable because of their detailed interviews and often very long durations. Examples include Elder's (1999) 30-year follow-up of individuals who had attended Oakland, California elementary schools and were enrolled in the Oakland Growth Study when in fifth and sixth grades and Furstenberg's (Furstenberg et al., 1987) 30-year panel study of Baltimore teen mothers who had enrolled in a teen parenting program in 1965.

Uses of Panel Surveys

To appreciate the analytic advantages of panel surveys, it is important to realize that the time dimension complicates analyses because: (1) characteristics of population elements may change over time, for instance, an individual may be single one month and married the next; and (2) the population itself may change in composition, with both sample units entering into and exiting from the population.

These complications, especially the first, give rise to a variety of objectives for analysis (Kish, 1986; Duncan and Kalton, 1987), including:

1. Estimates of population parameters (e.g., monthly rates of unemployment, public opinion regarding gun control) at

 http://dx.doi.org/10.1016/B978-0-08-097086-8.44040-7

distinct time points. The resulting time series of such estimates may be the input for further analysis; see, for example, Smith (1994).

2. Measurement of net change, defined as change at the aggregate level. An example is the change in the UK unemployment rate between two consecutive months or change in US public opinion regarding gun control before and after a gun-related event.
3. Measurement of various components of individual change, including: (i) gross change – change at the individual level between two time points (e.g., relating the poverty status of sample members in a given year to their poverty status ten years later); (ii) average change, or trend, for each individual over a period of time, with the average serving to smooth out the effects of isolated perturbations and measurement errors; or (iii) instability for each individual (e.g., the stability of locus of control over 25 consecutive weeks from a sample of elderly in Eizenman et al., 1997).
4. Aggregation of data for individuals over time. An example is the collection of incomes on an annual basis to relate childhood-long economic well-being to children's developmental outcomes (Blau, 1999).
5. Measuring the frequency, timing, and duration of events occurring within a given time period. Examples are the proportion of persons who were ill in the past two weeks and the average duration of their illnesses, and the complete fertility histories of postmenopausal women.

If the composition of a population is sufficiently stable to be treated as static for the time period of interest, it may be possible to collect the data required to meet all of these objectives from a single cross-sectional survey conducted at the end of the period. Crucial here is that errors of measurement are acceptably small. Unfortunately, respondents' memories are notoriously inadequate when a substantial time is involved or when the characteristics or events have a low degree of salience for the respondents (Bound et al., 2000). For example, respondents are often unable to recall important events such as unemployment (Mathiowetz and Duncan, 1984) or hospitalizations (Cannell et al., 1981) within periods as short as several months, and they cannot reliably recall subjective experiences (Moss and Goldstein, 1979). Thus, event data often need to be collected at several points throughout the period.

Repeated surveys can meet some of these analytic goals. Their particular strength is that at each round of data collection they routinely select a sample of the population existing at that time. They thus provide a series of cross-sectional estimates that can be used for objective (1) above. They can also be used to measure overall net change (2). The major limitation of a repeated survey is that it does not yield data to satisfy objectives (3) and (4): since elements are not explicitly included in several rounds, none of the components of individual change can be measured and individual data cannot be aggregated across rounds. Data on the frequency and timing of events in a specified period, as in objective (5), can be collected in a repeated survey, but with the measurement error problems noted above.

The major advantage of a panel survey over a repeated survey is its much greater analytical potential. It enables components of individual change to be measured, objective (3), and also the summation of a variable across time, objective (4). By providing high-quality measurements of the frequency, timing, and duration of events, panel surveys provide data useful for the estimating of event-history models (Tuma and Hannan, 1984; Allison, 1982; Yamaguchi, 1991).

A panel survey can be much more efficient than a repeated survey for measuring net change, objective (b). Let the net change be $y_2 - y_1$, where $y_1$and y_2 are the means of the variable of interest at times 1 and 2. Then the variance of the net change is $V(y_2 - y_1) = V(y_1) + V(y_2) - 2\rho[V(y_1)V(y_2)]^{1/2}$ where ρ is the correlation between y_1 and y_2. In a repeated survey with two independent samples, $\rho = 0$, but in a panel survey ρ is the correlation between an individual's y-values on the two occasions, which is often quite high. In this case, a panel survey will yield a much more precise estimate of net change, objective (b), than will a repeated survey of the same size. On the other hand, as discussed below, panel nonresponse between times 1 and 2 may result in more bias in the estimation of y_2 in a panel than repeated survey.

A panel survey also permits the collection of a wider range of data on each sampled element than is possible with a repeated survey. The amount of data collected from any one respondent on one occasion is limited by the burden imposed; however, different data can be collected on different rounds of a panel survey, thus providing the possibility of accumulating an extremely wide range of variables for each sampled element. In the US Survey of Income and Program Participation (SIPP), for instance, core data on income and program participation are collected on each round, and additional data on different topics (e.g., health care utilization and financing, pension and retirement issues, housing conditions) are collected on specific rounds only (US Bureau of the Census, 2000).

Some long-term panels have important intergenerational components, with data on children and their family contexts taken in early waves and measurements of the adult attainments of the children taken in later waves. Examples include population panels such as the National Longitudinal Survey youth panels, the PSID, the British Household Panel Survey (Institute for Economic and Social Research, 2000), the German Socio-Economic Panel, and more specialized data collections such as the Oakland Growth Study (Elder, 1999).

Problems with Panel Surveys

By attempting repeated interviews with the same sample, panel surveys have problems not found in single or repeated cross-sectional designs, the most important of which is panel nonresponse (initial-wave respondents may not respond in later waves). An additional potential problem with panel surveys is panel conditioning, where responses in a given interviewing round may be conditioned by participation in prior rounds of interviews.

Methods developed to cope with nonresponse bias include minimizing nonresponse in panel surveys and developing statistical adjustments for existing nonresponse. Existing panel surveys typically devote sizeable resources to maintaining high response rates, and sometimes are quite successful. For example, the National Longitudinal Survey of Youth conducted interviews in 1991 with 89% of the respondents in its initial,

1979, interview (MaCurdy et al., 1998). Losses in the British National Survey of Health and Development amounted to only 12% after 26 years (Atkins et al., 1981).

Incentive payments, respondent reports, persuasion letters, using administrative data for tracing, and collecting extensive contact information (e.g., on friends and relatives not living in the household who would know of address and telephone number changes) help minimize these problems (Freedman et al., 1980; Clarridge et al., 1978; Call et al., 1982).

As with any survey, sizeable nonresponse in a panel survey gives rise to concerns about nonresponse bias. The situation with the first wave of a panel survey corresponds to that with a cross-sectional survey in that very limited information is available on the nonrespondents. The situation with later wave nonresponse in a panel survey is, however, different: in this case a good deal of information is available about later wave nonrespondents from their responses on earlier waves. The earlier wave information can be used to investigate the possibility of nonresponse bias and to develop imputation and weighting nonresponse adjustments that attempt to reduce the bias (Kalton, 1986; Lepkowski, 1989).

With regard to conditioning, there is ample evidence from several surveys that initial responses in a panel survey differ substantially from those given in subsequent waves (Bailar, 1975, 1979; Ghangurde, 1982). In the case of the US Current Population Survey, estimates of unemployment from households entering the sample for the first time are almost 10% larger than the average over all eight monthly reporting periods. It is not clear whether there is more response bias in the initial or subsequent waves, because the repeated contact with respondents has ambiguous effects on the quality of the data. The crucial question, as yet unanswered for most phenomena reported in surveys, is whether it is merely the reporting of behavior or the behavior itself that is affected by panel membership.

It may be that data collected in subsequent panel waves is less biased, because repeated contact increases the probability that respondents understand the purposes of the study and are thus increasingly motivated to make the effort necessary to give more accurate answers. On the other hand, there is evidence from a validation study (Traugott and Katosh, 1979) that extended participation in a panel study on election behavior not only increased the accuracy of responses on voting behavior but may indeed have increased the amount of voting, so that the behavior of the panel was no longer representative of the behavior of the population at large.

It seems unlikely that panel participation has pervasive behavioral effects, especially when changes in the behavior under investigation require more effort than making a trip to the polls. For example, economic behavior such as work effort, saving, commuting, and home ownership are all unlikely to be affected by responses to occasional interviews. Responses to attitudinal questions may be affected by panel membership if participation stimulates interest in the subject matter of the survey.

The limited membership in a rotating panel acts to reduce the problems of panel conditioning and panel loss in comparison with a nonrotating panel survey, and the continual introduction of new samples helps to maintain an up-to-date sample of a changing population. Rotating panels are used primarily for the estimation of cross-sectional parameters, objective (1), for the estimation of average values of population parameters across a period of time, objective (2), and for measuring net changes, objective (3). A rotating panel survey will generally provide more precise estimates of point of time and, especially, of change parameters than a repeated survey of the same size. Moreover, a rotating panel survey will sometimes have a cost advantage over a repeated survey. This will occur when it is cheaper to conduct a reinterview than an initial interview, as for instance is the case in the US Current Population Survey where initial interviews must be conducted by personal visit whereas reinterviews on some waves may be conducted by telephone (US Bureau of the Census, 1978).

The ability of a rotating panel survey to measure components of individual change, objective (3), and to aggregate data for individuals across time, objective (4), is clearly restricted. Since rotating panels are not intended to serve these objectives, they can be designed to avoid the heavy expense of following movers that occurs with nonrotating panel surveys. Thus, for instance, the Current Population Survey employs dwellings, not households or persons, as the sampled units, so that there is no need to follow households or persons moving between panel waves.

In a split panel survey, the panel survey component can be used to measure components of individual change, objective (3), and to aggregate data for individuals over time, objective (4). Its permanent overlap aids in the estimation of net change, objective (2), between *any* two waves whereas the overlap in a rotating panel survey aids only in the estimation of net change between certain prespecified waves.

Both rotating and split panel survey designs provide samples of new entrants to the population and the capacity to use their panel survey components to check on biases from panel conditioning and respondent losses.

The Problem of Changing Populations

The composition of almost every population of interest, whether of individuals, families, firms, or housing units, changes over time. Individuals enter the population when they are born, immigrate, or attain the age or other status that is used to define the population of interest, and depart when they die, emigrate, move into institutions such as jails, nursing homes, or the military, or in some other way lose that status. Families are 'born' when children leave their parents and set up their own independent households or when a divorce or separation breaks up one family into two; they 'die' when all members of the original household die or when two households are merged into a single one through marriage or less formal living arrangements. Over a survey's time span an element may both enter and leave the population, and may do so more than once, as for instance in the case of a person who has several stays in a nursing home during the course of a survey of the noninstitutionalized population. Comparable changes through construction and demolition, or incorporation, merger, and bankruptcy apply to populations of dwellings and firms.

All surveys over time must address the issues raised by these changes in population composition (Duncan and Kalton, 1987). In a repeated survey the cross-sectional parameters of

objective (1) relate to the population as it exists at the time the sample is drawn for the particular round of the survey. This procedure reflects both the changing values of the variables under study and the changing population over the time period involved. The estimates are thus average values for a form of average population over time.

Panel studies have adopted a variety of strategies for coping with changing populations. The simplest are panel studies of birth cohorts of individuals in the population, where as many members as possible of the original sample are followed throughout the panel period. In effect, these panels ignore all problems of population composition change except death. Disregarding nonresponse and immigration, these studies represent their respective cohorts as they age, while they gradually cease to represent individuals in the original age range. The National Longitudinal Survey cohorts of Older Men and Mature Women are examples. As discussed above, multiple-cohort panel designs avoid this problem by including in subsequent interviewing waves a sample of new entrants into the population.

Panel designs such as that of the PSID, the British Household Panel Survey, and the European Community Household Panel surveys, contain a mechanism for adding to their samples individuals and families that are 'born' into the population, so they have the potential for maintaining representative samples of nonimmigrant individuals and families throughout their duration. For example, the PSID began with a probability sample of dwellings that, in turn, provides a representative sample of subunits within those dwellings: households, families, subfamilies, transfer program recipiency units, and individuals. The selection probability of each of these units is identical to the selection probability of the dwelling itself. Other panels composed these subsamples with known selection probabilities through other means. With a properly specified set of rules regarding the definition of units, newly formed subunits of interest (including individuals) enter into the sample with known selection probabilities and reflect corresponding changes that are taking place in the population at large, for example, Hill (1992).

Because they originate from existing panel households, newly formed families and individuals are more 'clustered' by family lineage in these designs than in repeated cross-sectional samples; however, the statistical inefficiency of this clustering is heavily outweighed by the analytic advantages of being able to link these newly formed units with information on their families of origin. Thus, information on children setting up independent households can be matched to reliably reported information on their parents, information on ex-spouses can be linked together if the marital split occurred during the panel period, etc. Immigration during the panel period is usually ignored although can be a serious problem for a long-term panel survey confined to a city or a local area, but it is a less serious problem for a national panel survey.

Examples of What Panel Surveys Have Found

To help convey the analytic advantages of panel surveys, we list in this section some prominent examples of panel-survey based analyses.

Poverty and Welfare Dynamics

Trends in annual US poverty rates (i.e., the fraction of the population with family cash incomes below a set of 'poverty thresholds' that vary with family size) are tracked through cross-sectional estimates based on the Current Population Survey. Net change from one year to the next in these rates rarely amount to as much as a single percentage point (US Bureau of the Census, 1999), producing perceptions that 'the poor' are an ever-present and little-changing group.

By applying event history methods to the time series of annual poverty measurements for PSID sample members, Bane and Ellwood (1986) characterized the nature and determinants of poverty experiences by the length of their 'spells' (i.e., continuous periods of poverty). They find that a clear majority (60%) of families who first begin a poverty experience do so for short (i.e., spells of 1 or 2 years) periods of time. On the other hand, a subset of poor families (14%) have longer-run (8 or more years) spells, and the remaining one-quarter (26%) have medium-length (3–7 years) spells. Thus, there is no single 'correct' characterization of poverty – transitory or persistent – since poverty experiences are a mixture of transitory and long-term.

By combining individual spells into simulated lifetime histories, Bane and Ellwood (1994) provide estimates of the likely total number of years of receipt for families just starting to receive cash assistance from the US Aid to Families With Dependent Children program. They find a roughly even distribution of first-time welfare recipients across the three time intervals; roughly one-third (36%) have very short welfare experiences, a third (35%) medium-length experiences, and the final third (29%) long-term receipt. With welfare, as with poverty, heterogeneity is a key feature, with many families using AFDC as short-term insurance, but a substantial fraction of recipients receiving long-term assistance.

Intergenerational Transmission of Economic Status

Correlations in earning between fathers and sons is sometimes treated as a useful measure of intergenerational (im)mobility. Solon (1992) argues that there are two important sources of bias in attempts to estimate such correlations: single year proxies for long-run economic status contain transitory fluctuations that, under plausible assumptions, impart a downward bias to the correlation estimates, and samples used in previous studies (e.g., Mormon brothers, white twins who served in the armed forces) tend to be peculiarly homogeneous, also resulting under plausible assumptions in a downward bias to estimates based on homogeneous than population-based samples.

Data from both the NLSY (in Zimmerman, 1992) and PSID (in Solon, 1992) have been used to gauge the likely biases. For example, Solon et al. (1992) find that increasing the measurement interval for economic status from one to several years causes their estimate of the father-son earning correlation to jump from 0.25, a number consistent with past studies based on single-year earnings measurement and homogeneous samples, to 0.45. Thus, intergenerational economic mobility appears to be substantially lower than had been depicted in

studies based on homogeneous samples and single-year measures of income or earnings.

The more specialized panel studies of Elder and Furstenberg provide much more detail on the process of intergenerational mobility. Using 30-year follow-up data on the Oakland Growth Study cohorts, Elder (1999) found in these children of the Great Depression strong associations among economic hardship, parental psychological well-being, and adolescent well-being in intact families.

Fathers who experienced job loss and economic deprivation were more distressed psychologically and prone to explosive, rejecting, and punitive parenting. Preschool-age children in these families, especially boys, were more likely to exhibit problem behaviors, while adolescent girls were more likely to have lower feelings of self-adequacy and to be less goal-oriented. Elder (1999) speculated that the gender and age differences reflected different experiences in families during the deprived times. Adolescent boys reacted to family economic hardship by looking for economic opportunities outside of the home. This time spent taking on responsibility in extra-family contexts reduced the time they spent with their families and may have provided a buffer to the effects of negative family interactions. Younger children and girls were unable to seek such extra-familial opportunities as readily and therefore did not have access to buffering opportunities.

Furstenberg et al. (1987) take a detailed look at intra- and intergenerational mobility in a panel study of a poor teen mothers participating in a program in a Baltimore hospital. Their 20-year follow-up revealed considerably diversity in the mothers' economic and demographic statuses, with most self-supporting but very few stably married. Most (60%) of the daughters of the teen mothers had not themselves become teen mothers and three-quarters enjoyed at least a modest degree of economic success. In contrast, fewer than half of the sons of the teen mothers had attained successful economic trajectories.

Unemployment and Labor Turnover

Both unemployment and job turnover are most naturally thought about in a 'spells' framework: how long does a spell of unemployment last before employment recommences? How long does a spell of employment with one firm last before the worker leaves to take (or look for) alternative employment? Given the inherently longitudinal nature of these processes, it is not surprising that panel surveys have played an important role in research on these topics. While much research on this topic has used administrative records, a panel survey has the advantages of including those who do not receive unemployment benefits, for comparison to recipients, and it continues observing spells after benefits have been exhausted (i.e., it measures total spells, not just insured spells), so one can observe changes in job-finding rates after benefits are exhausted.

An example is Katz and Meyer's (1990) study of the impact of unemployment insurance on unemployment duration. Katz and Meyer find that probability of recall declines as the duration of a spell increases, for both recipients and nonrecipients. New-job rates, however, are upward-sloping for recipients but relatively flat for nonrecipients. Moreover, there are spikes in both the recall and new-job hazard rates around 26 and 39 weeks (when benefits were typically exhausted in their sample period) for recipients but not for nonrecipients. Thus, not only is there evidence that the approaching end of benefits conditions recipients' job finding, but it also conditions firms' recall policies.

Antecedents of Life Events

There is great interest in understanding the consequences of important life events such as divorce, widowhood, unemployment, and retirement. Cross-sectional data provide comparisons of, for example, the living standards and labor supply of divorced women and 'otherwise similar' married women, or the health of unemployed or widowed men with 'otherwise similar' employed or married men. But panel surveys provide valuable post- and, interestingly, pre-event data on the same individuals.

For example, Johnson and Skinner (1986) use data from the PSID to examine work hours of women between seven years before and four years after divorce or separation. Consistent with other research, they find that the average work hours of these women rose by half (from 1024 to 1551 hours) between one year before and four years after the divorce or separation. But Johnson and Skinner (1986) also found a big jump (from 744 to 1024 hours) over the six-year period *prior* to the divorce or separation.

Zick and Smith (1991) analyze the economic antecedents and consequences of widowhood by comparing family-income trajectories of a control group of intact couples with widowed women and men between five years before and five years after the spouse's death. They too find differences prior to the event, with income changes over the five years *prior* to the death accounting for about one-quarter of the control-widow difference at $t+5$ and for fully half of the control-widower difference. A clear message from both of these analyses is that impending life events such as divorce and death produce measurable economic and social changes long before the events actually occur. An implication is that fairly long panels are needed to capture the complete dynamic.

Panic Disorder

Heather K Hood and Martin M Antony, Ryerson University, Toronto, ON, Canada

Abstract

Panic disorder (PD) is a condition associated with recurrent, unexpected panic attacks, characterized by sudden surges of physical arousal symptoms and fear. PD occurs frequently in the general population and is often associated with other psychological problems, including other anxiety disorders, depression, and substance-use problems. PD appears to stem from an interaction of biological, psychological, and social factors. This article begins with a review of diagnostic criteria, and then provides a brief summary of the biological and psychological factors involved in the onset and maintenance of PD. This article concludes with a review of effective medications and psychological treatments.

Panic disorder (PD) is an anxiety disorder associated with recurrent, unexpected panic attacks, characterized by sudden surges of physical arousal and fear. In addition, many individuals with PD develop agoraphobia to varying degrees. Agoraphobia is a fear of situations in which escape might be difficult or embarrassing, or in which help might be unavailable in the event of a panic attack.

The terms 'PD' and 'panic attack' first appeared in the diagnostic nomenclature with the publication of the third edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-III, American Psychiatric Association, 1980). Initially, panic attacks were seen primarily as a feature of agoraphobia. In the *Diagnostic and Statistical Manual of Mental Disorders-III* (DSM-III), agoraphobia could be diagnosed with or without panic attacks, and individuals who experienced unexpected panic attacks in the absence of agoraphobia received a diagnosis of PD without agoraphobia.

With the publication of the next edition of the DSM (e.g., DSM-IV, American Psychiatric Association, 1994), the relationship between PD and agoraphobia was reversed, such that PD was seen as the primary problem, and agoraphobia was viewed as a complication of PD. The disorder 'agoraphobia with panic attacks' was essentially replaced with 'PD with agoraphobia' to reflect the observation that, in clinical groups, agoraphobia can develop as a response to having unexpected panic attacks, rather than the other way around (Craske and Barlow, 1988).

More recently, with the release of DSM-5 (American Psychiatric Association, 2013), agoraphobia has been restored as a distinct diagnostic category. This change is supported by evidence indicating that 46–85% of people with agoraphobia do not have panic attacks (Faravelli et al., 2009). Other studies have not found a consistent temporal relationship between the onset of panic attacks and agoraphobic avoidance (e.g., Wittchen et al., 2008), calling into question the validity of agoraphobia as a secondary or subordinate diagnostic entity. In addition, agoraphobia without panic symptoms is associated with significant impairment and disability, and has a distinctive incidence, course, temporal progression, and treatment response compared to PD with or without agoraphobia (for a review, see Wittchen et al., 2010).

Definitions and Description

Panic Attack

DSM-5 (American Psychiatric Association, 2013) defines a panic attack as an abrupt surge of intense fear of discomfort that peaks within minutes. A panic attack must also be accompanied by at least 4 out of a list of 13 symptoms, which includes physical sensations (i.e., racing or pounding heart, sweating, trembling, shortness of breath, choking feelings, chest discomfort, nausea, dizziness, feelings of unreality or depersonalization, numbness or tingling sensations, hot flashes or chills) and cognitive symptoms (i.e., fear of losing control or going crazy, fear of dying).

Panic attacks are common in the general population and are also associated with a broad range of psychological problems. For example, people who experience intense worry may have a panic attack in response to a particular worrisome thought. Individuals who are fearful of a specific situation (e.g., seeing a spider, being in a high place) may experience panic attacks when confronted with these situations. In addition, the presence of cooccurring panic attacks in the context of other psychological disorders have been associated with increased severity, distress, and poor response to treatment of the principal diagnosis (Craske et al., 2010). Panic attacks may also occur in the absence of any obvious cue or trigger. In fact, the hallmark symptom of PD is the presence of panic attacks that occur out of the blue.

Panic Disorder

People who suffer from PD experience recurrent unexpected or uncued panic attacks. In addition, they must experience, for at least 1 month, one or more of the following: (1) persistent worry about having more panic attacks or worry about the implications or consequences of the attacks (e.g., that an attack will lead to a heart attack, death, fainting, diarrhea, vomiting, embarrassment, or some other catastrophe); or (2) a significant maladaptive change in behavior related to the attacks (e.g., avoidance of certain situations or activities). Finally, before assigning a diagnosis of PD, the clinician must establish that the panic attacks are not directly related to another psychological problem (e.g., a specific phobia), a medical condition

(e.g., hyperthyroidism), or use of a substance (e.g., cocaine, caffeine). PD may be diagnosed with or without agoraphobia.

Agoraphobia

A significant proportion of individuals suffering from PD develop agoraphobia, a fear of situations in which escape might be difficult, or in which help might not be available in the event of a panic attack (American Psychiatric Association, 2013). DSM-5 requires that individuals with agoraphobia report fear or anxiety in at least two of the following five situations: (1) using public transportation (e.g., driving, flying, or traveling on buses or trains), (2) being in open spaces (e.g., bridges, parking lots), (3) being in enclosed places (e.g., concerts, movies, shopping malls), (4) standing in a line or being in a crowd, or (5) being outside the home alone (American Psychiatric Association, 2013). For some individuals with agoraphobia, it is the distance from home, rather than the situation itself, that determines the level of fear and avoidance. For example, driving may be difficult, but only if the car ventures more than a few kilometers from home. For many people who suffer from agoraphobia, entering feared situations is easier if accompanied by a safe person, such as a spouse, family member, or close friend. In extreme cases, agoraphobia may be associated with a complete inability to leave the home, even when accompanied.

In addition to the obvious avoidance associated with agoraphobia, individuals with PD often engage in more subtle forms of avoidance. For example, a person might see a movie in a theater, but only if sitting in an aisle seat, near the exit. Or an individual might agree to ride a bus only while engaging in distracting behaviors such as reading or listening to a portable radio. Individuals with PD may also carry objects with them to feel safer, including medication, extra money in case of an emergency, or a portable telephone. Finally, they may engage in overprotective behaviors such as frequently checking their heart rate or blood pressure.

Epidemiology, Onset, and Demographics

PD begins on average when a person is in his or her mid- to late-20s, although onset can occur any time between childhood and late in life (Kessler et al., 2005). Risk factors include a period of life stress preceding the first attack, being female, and a history of either substance abuse or dependence (Antony and Swinson, 2000).

In the National Comorbidity Survey Replication (a study of over 9000 Americans in the general population), 4.7% of individuals reported symptoms meeting criteria for PD with or without agoraphobia at some time in their life (Kessler et al., 2006). In the same study, the lifetime prevalence of agoraphobia without history of PD was 1.4%. Although some studies report substantially higher prevalence rates of agoraphobia among community samples, agoraphobia is rarely diagnosed separately from PD in clinical settings (Wittchen et al., 2010).

People with PD report impairment across a broad range of life domains including work, recreation, and social functioning (Olatunji et al., 2007). Furthermore, PD is associated with enormous costs to sufferers and to society, in the form of increased health care utilization, lost wages, and time off work (e.g., Greenberg et al., 1999). In fact, PD is associated with higher rates of medical utilization at general and specialist settings compared to all other anxiety disorders (Deacon et al., 2008). In addition, PD is associated with a higher risk of developing other psychological problems, including other anxiety disorders, depression, certain personality disorders (e.g., dependent, avoidant), and substance-use disorders (for a review, see Antony and Swinson, 2000).

Biological Approaches to Understanding PD

Biological Models of PD

Most biological approaches to understanding PD have assumed a dysfunction in one or more neurotransmitter systems, including norepinephrine (NE), serotonin (5-HT), and cholecystokinin (CCK). In addition, theorists are increasingly seeking to understand the contribution of genetic and neuroanatomical factors involved in the pathogenesis of PD (e.g., Maron et al., 2010).

Perhaps the most influential biological model of PD in recent years has been Donald Klein's suffocation alarm model (Klein, 1993), which proposes that panic attacks are caused by a pathological misfiring of the suffocation alarm system. According to Klein, humans are equipped with two types of alarm reactions. The first is controlled by the hypothalamic–pituitary–adrenal axis and is responsible for dealing with real or perceived emergency situations. It is this alarm system that is activated when an individual is confronted with a feared object or situation.

The second alarm system is the suffocation alarm system, which is mediated by an area of the brain known as the *locus ceruleus*. This alarm system is triggered by increased levels of carbon dioxide in the blood, a sign that individuals might be in a small enclosed area, forced to breathe their own exhaled air, which is rich in carbon dioxide. Klein hypothesized that unexpected panic attacks occur when an individual has a pathologically lowered threshold for the activation of the suffocation alarm system. Presumably, the brains of such individuals are prone to mistakenly conclude that there is not enough air to breathe. Evidence regarding Klein's model has been mixed (for a review, see Antony and Swinson, 2000), particularly, with regard to the hypothesized causal role of respiratory symptoms (Vickers and McNally, 2005).

Evidence Regarding Biological Approaches to Panic

Despite inconsistent evidence for Klein's model, there are many studies supporting the view that biological processes are involved in the pathophysiology of PD. PD tends to run in families and evidence from twin studies consistently showing that genetics plays a significant role in the transmission of PD across generations (Finn and Smoller, 2001). Findings from brain imaging studies suggest that the temporal areas of the brain, including the hippocampus and amygdala, as well as the medial prefrontal cortex, are involved in the experience of panic attacks and fear (de Carvalho et al., 2010).

Evidence regarding the role of neurotransmitters in PD has included studies of altered receptor functioning, levels of particular neurotransmitters and related metabolites, and responses to substances that are known to cause changes in neurotransmitter levels. Among neurotransmitters, NE is the one most often implicated in PD and agoraphobia (Kalk et al., 2011), although other neurotransmitter systems, such as 5-HT (Maron and Shlik, 2006) and CCK (Zwanzger et al., 2012), appear to also play a role. There is evidence that levels of NE metabolites are elevated in the peripheral, but not in the central nervous system of individuals with PD (Kalk et al., 2011) and of elevated NE receptor sensitivity in people suffering from PD (Nutt, 1989). In addition, drugs that block the reuptake of NE, including the class of drugs known as serotonin–norepinephrine reuptake inhibitors (SNRIs) such as venlafaxine and duloxetine, appear to be effective for treating PD (Pollack et al., 2007).

Finally, a large number of studies have shown that certain substances that affect the NE system are more likely to trigger panic attacks in people with PD than in various comparison groups. Infusions of sodium lactate, carbon dioxide inhalation, and yohimbine injections have all been shown to trigger panic attacks. However, it should be noted that psychological and contextual factors, such as perceived control over the procedure, the presence of safety cues, and the expectations of physical arousal, can influence whether an individual will experience a panic attack following exposure to these substances (Sanderson et al., 1989; Telch et al., 2011).

Psychological Approaches to Understanding PD

Psychological Models of PD

Attempts to explain PD using a psychological framework have come from a broad range of theoretical perspectives, including cognitive theory, learning theory, and psychodynamic theory. However, the most influential of these models have been those developed by cognitive and behavioral theorists such as David M. Clark (1986) and David H. Barlow (1988, 2002).

From a cognitive behavioral perspective, PD is viewed as being maintained by a fear of benign physical sensations. For example, according to David Clark's cognitive model of PD, panic attacks stem from a tendency to misinterpret normal physical sensations (e.g., racing heart, dizziness) as indicating some immediate danger. As a result of interpreting these sensations as being threatening, the symptoms escalate, leading to further catastrophic interpretations and predictions. Very quickly, the symptoms spiral into a full-blown panic attack, seemingly out of the blue. Clark and other cognitive theorists acknowledge that biological factors may also contribute to the experience of panic. The sensations that initially start the panic cycle may be caused by caffeine, intense emotions, exercise, hormonal changes, fatigue, hunger, hyperventilation, attention to bodily feelings, or other factors. Consistent with the cognitive behavioral view, 70% of individuals with PD report that their panic attacks are triggered by a physical sensation (Breitholtz et al., 1998).

Evidence Regarding Psychological Approaches to Panic

A number of studies have confirmed that people with PD are fearful of the physical sensations associated with panic attacks, compared to people without PD and people with other anxiety disorders (McNally, 2002). In addition, researchers have demonstrated that people with PD are more likely than others to interpret ambiguous physical sensations as a sign of some impending physical or mental disaster and to believe these thoughts quite strongly (Clark et al., 1997).

Numerous studies have also found that people with PD have information-processing biases that are consistent with their fears. For example, a number of studies have found that PD is associated with a heightened ability mentally to track physical sensations such as heart rate (e.g., van der Does et al., 2000). In addition, results from studies of attention and memory have also been consistent with psychological models of PD. Compared to people without PD, individuals with PD attend more to threatening faces and words (Reinecke et al., 2011), and are more likely to show threat-related biases in explicit (i.e., conscious, intentional recollection), but not implicit (i.e., unintentional, automatic processing), memory (Mitte, 2008).

In summary, individuals with PD are typically more fearful of and more vigilant for panic-related sensations, compared to people without PD. PD is also associated with a tendency to hold fearful beliefs about panic-related sensations, and to show biases in attention and memory for threat-related information.

Treatment of PD

The recently updated American Psychiatric Association (2009) practice guidelines for the treatment of PD discuss important issues in the assessment and treatment of this condition, and reviews the main approaches that have been shown to be useful for treating PD. Essentially, these approaches include treatment with medications, particularly selective serotonin reuptake inhibitors (SSRIs) and SNRIs medications, and treatment with cognitive behavior therapy (CBT). A review of studies on the relative and combined effects of these interventions is available elsewhere (e.g., Koerner et al., 2012). A brief summary of the major findings is provided below.

Medication Treatments

A large number of controlled clinical trials have established that certain medications are useful for treating PD with and without agoraphobia. Controlled trials have established that SSRIs (e.g., fluoxetine, fluvoxamine, sertraline, paroxetine, citalopram) and SNRIs (e.g., venlafaxine) are also useful for treating PD; in fact, the SSRIs and SNRIs are now often considered to be the pharmacological treatments of choice for this condition because of the lower rates of adverse effects and withdrawal symptoms with SSRIs and SNRIs compared to some other medication classes (Mitte, 2005). Although tricyclic antidepressants, and imipramine in particular, have

also been shown to be an effective treatment for PD (e.g., Barlow et al., 2000), they are often associated with pronounced adverse side effects, limiting their clinical utility (Mavissakalian et al., 2002). In addition, monoamine oxidase inhibitors (MAOIs), such as phenelzine, have been demonstrated in a limited number of controlled trials to be useful in treating PD (Buigues and Vallejo, 1987). However, MAOIs are associated with an increased risk of drug interactions, necessary dietary restrictions when taking the medications, and only modest response rates; as such, MAOIs are generally not recommended as a first line treatment for PD (American Psychiatric Association, 2009). Studies with high-potency short-acting (e.g., alprazolam) and long-acting (e.g., clonazepam) benzodiazepine anxiolytics have consistently shown these medications to be effective as well (Moylan et al., 2011), although there remains a significant risk of withdrawal and rebound anxiety upon discontinuation (Chouinard, 2004).

There is now consistent evidence that SSRIs and SNRIs are preferred medication options for PD. However, other medication classes may be preferable for some patients. Choosing among medications for a particular individual usually depends on factors such as potential side effects, possible problems during discontinuation (e.g., rebound anxiety), the patient's previous history of treatment response, the cost of the drug, and potential interactions with other medications, substances, or medical illnesses.

Cognitive Behavior Therapy

CBT for PD includes five main types of strategies: (1) psychoeducation about the nature of anxiety and panic; (2) exposure to feared situations such as crowds, public transportation, and being away from home alone (i.e., *in vivo* exposure); (3) exposure to exercises that trigger feared sensations (e.g., overbreathing or spinning to induce feelings of dizziness); (4) cognitive restructuring (i.e., systematically considering evidence that contradicts fearful thinking); and (e) relaxation-based strategies (e.g., learning to slow down one's breathing). Most empirically-supported CBT protocols (e.g., Barlow and Craske, 2006; Clark et al., 1999), include various combinations of these strategies.

A number of comprehensive reviews on CBT for PD have been published (e.g., Koerner et al., 2012; Taylor, 2000). Generally, there is little evidence that it is necessary to include all five treatment components to achieve maximum results. *In vivo* exposure to feared situations appears to be particularly important for treating individuals who are agoraphobic. Recently, the inclusion of relaxation-based strategies, including breathing retraining, have been called into question as studies have failed to demonstrate an additive effect of including breathing retraining into CBT treatment protocols (Schmidt et al., 2000).

Although CBT for PD typically consists of 10–15 weekly sessions, a number of recent studies suggest that gains can be made relatively quickly, with a minimal investment of therapist time. For example, therapist-administered CBT via telephone (Swinson et al., 1995) and video-conferencing (Bouchard et al., 2004) have been successfully used to treat people who do not have easy access to a therapist. In addition, internet-based (Carlbring et al., 2005) and bibliotherapy (Febbraro, 2005) self-help have also been reported to be an effective alternative to therapist-administered CBT requiring minimal therapist contact (for a review, see Lewis et al., 2012). Further, a single session of CBT has been shown to prevent the onset of PD in a significant percentage of individuals who present to hospital emergency rooms with a panic attack (Swinson et al., 1992). Finally, a number of studies have found that brief CBT lasting only five sessions (Otto et al., 2012) can produce clinically significant improvements in PD symptoms comparable in magnitude to those obtained with standard treatment protocols (*see* Cognitive Behavioral Therapy).

Combination Treatments

Several meta-analyses of randomized controlled trials have consistently demonstrated that medications, CBT, and their combinations are effective for treating PD (e.g., Furukawa et al., 2006; Mitte, 2005). Although some studies have demonstrated a slight advantage for combination treatments at the end of the acute treatment phase, it should be noted that most studies have focused primarily on the short-term effects of treatment over a period of only 2 to 3 months, and combined treatments are no more effective than standard monotherapy at long-term follow-up (Furukawa et al., 2006). In fact, the studies that have examined the relative and combined effectiveness of CBT with either imipramine (Barlow et al., 2000), alprazolam (Marks et al., 1993), or fluvoxamine (Sharp et al., 1996) have consistently found that individuals who received CBT (alone or in combination with medication) were more likely to maintain their gains over the long term than individuals who received only medication or placebo treatment. In addition, CBT has been used successfully to prevent relapse and facilitate discontinuation of benzodiazepines among individuals with PD (Otto et al., 2010). As such, it has been suggested that combined approaches may be most effective when CBT is introduced during discontinuation of pharmacological treatment to protect against relapse (Otto et al., 2009).

Taken together, the literature on treating PD suggests that CBT and pharmacotherapy are both effective treatments in the short term. However, there is evidence that CBT is a more effective treatment for ensuring that gains are maintained over the long term.

Abstract

This article is aimed to give a short overview over the most important features and research findings about panic disorder and agoraphobia. The diagnostic criteria will be discussed reviewing the changes in the history of the Diagnostic Statistical Manual for Mental Disorders. Epidemiology will be reviewed within development and maintenance factors. Different theoretical models will be discussed and the evidence-based treatment approach will be explained. Possible mechanisms of change are explained and the article ends with a short overview of clinical implications and future directions of research.

Definition and Diagnostic Criteria

Panic Disorder

Panic disorder and agoraphobia can be disabling conditions, which are associated with significant interference in occupational and social functioning (Schmidt et al., 2013). Certain degrees of anxiety are adaptive in daily life and can protect us when confronted with dangerous situations. Thus, we can think of the continuum from worry to anxiety to panic as an alarm system designed to protect us from danger. However, when this alarm system goes off even in relatively safe situations and we fear the alarm system itself, this can have a major negative impact on the individual's daily functioning.

According to the Diagnostic and Statistical Manual of Mental Disorders fifth edition (DSM-5), panic disorder refers to experiencing recurrent and unexpected panic attacks (Criterion A). A panic attack is an abrupt surge of intense fear or intense discomfort that reaches a peak within minutes, and during which time four or more of a list of 13 physical and cognitive symptoms occur (American Psychiatric Association (APA), 2013). This includes palpitations, pounding heart, or accelerated heart rate; sweating; trembling or shaking; sensations of shortness of breath or smothering; feelings of choking; chest pain or discomfort; nausea or abdominal distress; feeling dizzy, unsteady, lightheaded, or faint; chills or heat sensations; paresthesia; derealization or depersonalization; fear of losing control; and fear of dying. The term 'recurrent' refers to have experienced more than one panic attack and 'unexpected' refers to the fact that no obvious trigger has elicited the panic attack. Panic attacks can even occur when the individual is relaxing or during nighttime. The distinction between expected and/or unexpected panic attacks has to be made carefully, based on open and structured questioning about the attacks and circumstances. In the United States and Europe, approximately one-half of individuals with panic disorder have expected panic attacks as well as unexpected panic attacks (Craske et al., 2010). Thus, according to the DSM-5, the presence of expected panic attacks does not rule out the diagnosis of panic disorder (APA, 2013).

However, most patients with panic disorder experience a mixture of different types of panic attacks (Schmidt et al., 2014). During the onset of panic disorder, panic attacks occur spontaneously and unexpectedly. However, as time progresses, patients are often able to establish a link between panic and a variety of situations, which trigger their panic attacks at an earlier stage, so that panic attacks appear to be more situationally bound over the course of panic disorder.

The frequency and severity of panic attacks can vary widely and depend largely on the individual coping style and avoidance behavior. In panic disorder, experiencing panic attacks is accompanied by frequent worries about the next panic attack and the possible consequences. These consequences include the presence of a life-threatening illnesses (e.g., cardiac disease, seizure disorder) or social concerns, such as embarrassment or fear of being judged negatively by others because of visible panic symptoms and concerns about mental functioning such as 'going crazy' or losing control (Criterion B) (APA, 2013). Often maladaptive behaviors occur to minimize the occurrence of panic attacks. Examples include avoiding physical exertion, reorganizing daily life to ensure that help is available in the event of a panic attack, restricting usual daily activities, and avoiding situations, such as using public transportation or shopping. If intense fear of multiple situations is present, a separate diagnosis of agoraphobia is given.

Agoraphobia

The essential feature of agoraphobia is marked or intense fear or anxiety triggered by real or anticipated exposure to a wide range of situations (Criterion A; APA, 2013). The diagnosis requires the occurrence of symptoms in at least two of the following five situations: (1) using public transportation, such as automobiles, buses, trains, ships, or planes; (2) being in open spaces, such as parking lots, marketplaces, or bridges; (3) being in enclosed spaces, such as shops, theaters, or cinemas; (4) standing in line or being in a crowd; or (5) being outside of the home alone (APA, 2013). When experiencing fear and anxiety cued by such situations, individuals typically experience thoughts that something terrible might happen (Criterion B). Individuals frequently believe that escape from such situations might be difficult (e.g., 'cannot get out of here') or that help might be unavailable (e.g., 'there is nobody to help me') when paniclike symptoms or other incapacitating or

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21014-3

embarrassing symptoms occur. 'Paniclike symptoms' refer to any of the 13 symptoms included in the criteria for panic attack, such as dizziness, faintness, and fear of dying. 'Other incapacitating or embarrassing symptoms' include symptoms such as vomiting and inflammatory bowel symptoms, as well as, in older adults, a fear of falling or, in children, a sense of disorientation and getting lost.

Fear or anxiety is evoked nearly every time the individual comes into contact with the feared situation (Criterion C). Thus, an individual who becomes anxious only occasionally in an agoraphobic situation (e.g., when standing in line on only one out of every five occasions) would not be diagnosed with agoraphobia (Craske et al., 2010; Wittchen et al., 2010).

From DSM-IV to DSM-5

The definition and diagnostic criteria of panic disorder and agoraphobia have undergone significant changes over time in the DSM (Schmidt et al., 2014). In particular, the description of the relationship between panic disorder and agoraphobia has undergone interesting changes within the DSM. While Marks (1970) originally suggested to classify agoraphobia as a phobic disorder arising from fears of public places that may or may not occur with panic attacks, as was done in the DSM-III (American Psychiatric Association (APA), 1980), over time researchers increasingly recognized that agoraphobia can occur as a consequence of panic attacks and in the DSM-III-R and DSM-IV the relationship between these conditions was reversed. Agoraphobia was considered to be a consequence of panic attacks and thus, agoraphobic behaviors were classified more as panic-related sequelae (Frances et al., 1993; Goldstein and Chambless, 1978; McNally, 1994).

In the DSM-5 (APA, 2013), agoraphobia is classified as a distinct disorder from panic disorder. This means that patients can receive either a diagnosis of panic disorder or a diagnosis of agoraphobia, or a comorbid diagnosis of panic disorder and agoraphobia. The separation of panic disorder and agoraphobia is based on large cohort and prospective studies wherein it is shown that agoraphobia exists in individuals who never experienced any panic attacks or paniclike symptoms (Faravelli et al., 2008; Fava and Morton, 2009; Wittchen et al., 1998). For a recent review see Emmelkamp and Powers (2009). A detailed analysis of the prospective reports as well as analysis of the incidence patterns of agoraphobia indicate that a substantial percentage of individuals with this diagnosis show no history of panic or paniclike symptoms (Wittchen et al., 2008). However, fairly often, panic disorder and agoraphobia are comorbid conditions. For a more complete discussion on the diagnostic changes between DSM-IV and DSM-5 with regard to the diagnosis of panic attacks, panic disorder, and agoraphobia see Schmidt et al. (2013).

Prevalence

The 12-month prevalence of panic disorder ranges between 1% and 3% across the United States (Kessler et al., 2012, 2005) and Europe (Goodwin et al., 2005; De Graaf et al., 2012). The 12-month prevalence of agoraphobia is approximately 1.7% in adolescents and adults (Kessler et al., 2012; Wittchen et al., 2011). Onset of agoraphobia can occur during childhood but the most vulnerable periods to develop the disorder are late adolescence and early adulthood (Beesdo et al., 2009; Bittner et al., 2007). The gender ratio is 2:1 with females experiencing twice as often agoraphobia as men (Wittchen et al., 2010). This may be for several reasons: (1) males (especially young) tend to be less willing to openly discuss agoraphobic fears and avoidance behavior, (2) because of this desire to not appear 'weak,' they might expose themselves to the feared situations with fear reduction over time as an unintended consequence, or (3) they use other methods to enter the feared situations (alcohol/substances).

Development and Maintenance Factors

Development and Avoidance Behavior

Epidemiological research has investigated potential risk factors for panic disorder. As in most psychiatric disorders, a diathesis-stress model is commonly used to explain the development and maintenance of the disorder (Roy-Byrne et al., 2006).

While panic attacks are quite common in the general population, only a small percentage of people develops panic disorder (Emmelkamp and Powers, 2010). While most people who experience a panic attack during their lifetime just go on with their life, a small percentage starts worrying about their next panic attack and their perceived consequences. There is some evidence that this panic-related apprehension is one of the key factors in developing panic disorder (Telch et al., 1989). Panic appraisal is usually considered to consist of three different aspects: (1) perceived likelihood of panic occurrence, (2) the perceived negative consequences, and (3) the perceived efficacy in panic coping (Telch et al., 1989). There are some indications that these aspects of panic appraisal are the best predictor for agoraphobic avoidance (Smits et al., 2004; Telch et al., 1989; Cho et al., 2007).

Other researchers emphasize the importance of cognitive factors in the development of panic disorder (Beck and Emery, 1985; Clark, 1986), for example, anxiety sensitivity (McNally, 2002). Anxiety sensitivity is referred to as the fear of benign bodily sensations, which is caused by anxiety – also referred to as fear of fear (Goldstein and Chambless, 1978; Reiss et al., 1986) and has long been considered a specific vulnerability of panic disorder (White et al., 2006). Anxiety sensitivity is mostly conceptualized as a trait that remains relatively stable over time; although there are more studies showing that anxiety sensitivity decreases following treatment (Naragon-Gainey, 2010; Smits et al., 2008).

Currently, it remains unclear why some individuals with panic attacks start avoiding situations while others do not (Emmelkamp and Powers, 2010). Most individuals with agoraphobia experience some panic attacks or show some signs of anxiety before the onset of panic disorder and/or agoraphobia (Fava et al., 1992). The initial onset of agoraphobia is typically before the age of 35 years. There is a latent incidence risk in late adolescence and early adulthood. The mean age for onset of agoraphobia without preceding panic attacks is between 25 and 29 years (Nocon et al., 2008; Wittchen et al., 2010). Usually the course of agoraphobia is chronic and if not treated the remission rate is low (10%) (Emmelkamp and Wittchen, 2008). With increasing severity of agoraphobic symptoms, chronicity

increases and full remission rates decrease. In the long-term, a range of comorbidity may complicate the course of agoraphobia; depressive disorders, substance use disorder and traits of personality disorders. The clinical feature of agoraphobia is relatively consistent across the life span, although situations, which trigger fear and avoidance as well as the type of cognitions, may change. For example, for children being outside their home alone is the most frequently feared situation, whereas in adults standing in line in a shop and being in open spaces are most often feared (Wittchen et al., 2010). Common cognitions in children include becoming lost while in older adults cognitions focus more on falling.

Although panic severity does not predict the development of agoraphobia, the patients' exaggerated likelihood estimation of panic occurrence in situations is the best predictor of agoraphobic avoidance accounting for almost 80% of variance in avoidance behavior (Rachman, 1994; Telch et al., 1989). In a recent trial, it was shown that initial changes during therapy in agoraphobic cognitions predict later changes in avoidance behavior (Meyerbroeker et al., 2013).

Twin studies show 40% heritability with contributions from common familial environmental effects (<10%) and unique environmental effects (>50%) (Roth et al., 1984). It has further been suggested that an anxious temperament, which is characterized by neuroticism functions as an important risk factor (Watanabe et al., 2005).

Life Events and Stress

There is increasing evidence that life events often precede the onset of panic disorder. In a number of studies, it was found that up to two-thirds of patients with panic disorder experienced a significant personal loss in the year preceding the onset of panic disorder (Faravelli and Pallanti, 1989; Milrod et al., 2004; Pollard et al., 1989; Scocco et al., 2007). Most individuals report stressors in the months before their first panic attack, which can be interpersonal stressors, stressors related to physical well-being, or work-related stressors. Another important aspect is that childhood experiences of sexual, physical, and/or emotional abuse. These experiences are commonly reported in individuals with panic disorder (Roy-Byrne et al., 2006; Schade et al., 2004).

Comorbidity

High comorbidity rates have been found in individuals with anxiety disorders for substance abuse, especially alcohol abuse (Grant et al., 2004). In patients with an alcohol-related substance use disorder, an overall rate of more than 42% was found to have a comorbid anxiety disorder (Schneider et al., 2001). Most prevalent were social phobia (14%), agoraphobia (13%), and panic disorder (5%). The relationship between substance abuse and panic disorder and agoraphobia seems to be reciprocal (Emmelkamp and Powers, 2010). Individuals are often convinced that the use of alcohol reduces their anxiety and substance abuse might be attributed to anxiety as a form of self-medication (Zimmerman and Chelminski, 2003). On the other hand, symptoms of panic and anxiety are common symptoms during withdrawal and should be distinguished from primary anxiety disorders (Emmelkamp and Vedel, 2006).

Medical Conditions

Panic disorder is commonly associated with numerous medical conditions and symptoms such as dizziness, cardiac arrhythmias, apnea, hyperthyroidism, asthma, COPD, and irritable bowl syndrome (APA, 2013). However, it remains unclear, what the exact nature of this relation is (cause or effect) and it might be that some physical symptoms just overlap and are due to the medical condition.

Theoretical Background

Depending on theoretical background, different models have been developed to explain the development and maintenance of panic disorder and agoraphobia. Although, different theoretical background often lead to different treatment models. In panic disorder and agoraphobia in general the treatment consists of the same basic components.

Cognitive Model

As in most anxiety disorders, the appraisal of threat is central to the cognitive theory of panic disorder and agoraphobia (Beck and Emery, 1985; Salkovskis et al., 2007). One possible explanation is that panic occurs because individuals are appraising normal somatic symptoms of anxiety as excessively threatening (Clark, 1986). According to the cognitive model of panic disorder, panic can be classified as an anxiety, which focuses on somatic sensations, which are usually increased while experiencing anxiety (Salkovskis, 2007). According to this view, the cognitive hypothesis of panic is based on the premise that individuals who are experiencing recurrent panic attacks do so because they have a tendency to misinterpret bodily sensations as dangerous or life threatening. Thus, in long-term individuals fear their fear.

Behavioral Model

In panic disorder, the pairing of intense fear and experiencing bodily sensations at the same time is central to develop the disorder in the classical conditioning paradigm. According to a classical conditioning model, the occurrence of one of the symptoms (e.g., palpitations) leads 'automatically' to the other (anxiety: 'I might have a heart attack') thus provoking a full panic attack. According to the conditioning paradigm, the same holds true for the development of panic disorder and agoraphobia. In the comorbid condition, panic attacks are correlated with certain situations, which in the long run lead to more paniclike symptoms leading to a situational-bound panic attack. The maintenance of anxiety disorders in general can be explained by operant conditioning when leaving the feared stimulus leads to reward (Emmelkamp et al., 1995).

Different theories have been discussed to explain the major effects of exposure therapy in anxiety disorders (Telch et al., 2014). It has been argued that exposure can be explained by means of habituation (Marks, 1978). According to Wolpe (1958), the effects of exposure therapy can be explained by means of reciprocal conditioning: the central idea is that fear could be eliminated by pairing a patient's fear response with

a physiological response, which was incompatible with the fear response (e.g., relaxation), and which would lead to inhibition of the original fear response. In experiments all over the world, it was shown that relaxation was not a necessary component to achieve meaningful fear reduction (Emmelkamp, 1982). In more recent views, treatment success is explained in terms of a learning paradigm (Bouton, 2000; Craske et al., 2008).

Biological Model

As in most other psychiatric disorders, multiple gene interactions are central to the biological models (Craske and Barlow, 2008). It is suggested that relatively broad or nonspecific genetic factors influence the vulnerability to panic and anxiety. This gene interaction probably explains why panic disorder and agoraphobia tend to run in families. For a recent review, concerning the debate about gene–environment interaction in panic disorder see Battaglia (2013).

Mechanisms of Change

Panic Appraisal

There seems to be preliminary evidence for cognitive mediation during cognitive behavioral therapy (CBT) in panic disorder (Hofmann et al., 2007). In a randomized controlled trial, 91 subjects were allocated to receive CBT alone, imipramine alone, CBT plus imipramine, or CBT plus placebo. Individuals who received one of these interventions were assessed before and after acute treatment, and after a 6-month maintenance period. It was shown that changes in panic-related cognitions-mediated changes in panic severity only in treatments that included CBT. This is in line with the findings of Fernandez-Arias et al. (2013) who argued not to combine psychological treatment with pharmacological treatment. First results are promising, but more research is needed to investigate the assumed mechanisms of change in exposure-based treatments in panic disorder. Panic appraisal has been found to play an important role in the development and maintenance of panic disorder and agoraphobia, but more research is needed to replicate and further extend these findings and investigate whether these findings are specific for panic disorder and agoraphobia or whether anxiety appraisal might be a more general factor across anxiety disorders.

Anxiety Sensitivity

From a cognitive perspective, anxiety sensitivity can be considered a significant factor in the development and maintenance of panic disorder (Barlow, 2002). Several other studies suggest that anxiety sensitivity mediates improvement in the treatment of panic disorder (Cho et al., 2007; Hofmann et al., 2007; Smits et al., 2004). For example, one study suggested that changes in anxiety sensitivity fully mediated improvement in patients with panic disorder after CBT when compared to a wait list control condition and partially mediated improvement in patients with agoraphobia (Smits et al., 2004). These results were stable at 6-months follow-up (Cho et al., 2007). In another study, it was shown that reductions in anxiety sensitivity preceded reductions in panic symptoms (Smits et al., 2008), thus meeting the temporal precedence criteria as a mediator of change in panic disorder. Anxiety sensitivity is associated with most anxiety disorders, but a particularly strong relationship between panic attacks and anxiety sensitivity has been demonstrated (Bentley et al., 2013). Anxiety sensitivity has also been shown to predict spontaneous panic attacks (Maller and Reiss, 1992; Plehn and Peterson, 2002).

In a large recent treatment study with 361 individuals with panic disorder, effect sizes showed that the greatest changes in anxiety sensitivity occurred at early treatment stages (Gallagher et al., 2013). Additionally, it was shown that anxiety sensitivity predicted changes in panic disorder symptoms, thus indicating that anxiety sensitivity might be a mechanism of change, which is particularly important during the early stages of treatment.

In terms of transdiagnostic approaches, anxiety sensitivity might be a marker across anxiety disorders. There is more research needed to investigate whether the above-mentioned findings can be replicated in other anxiety disorders. These findings are interesting in times of unified protocols and more dimensional perspectives of mental disorders. The above-mentioned findings are important for understanding the mechanisms of change in specific anxiety disorders, but research has also shown that anxiety sensitivity plays an important role across other anxiety disorders (Vanden Bogaerde and De Raedt, 2011).

Evidence-Based Treatment Approaches

Guidelines

According to the NICE guidelines (National Institute for Health and Clinical Excellence, 2011), there is a consensus that empirically supported psychological treatments are the treatment of choice for panic disorder and agoraphobia. This can be combined with pharmacological treatments, which can produce better results in reducing relapse rates and improving maintenance of gains (Barlow et al., 2000; Otto et al., 2005), although this has been questioned recently (Fernandez-Arias et al., 2013; Hofmann et al., 2007). Please see also the section about pharmacological treatment and the paragraph about mechanisms of change.

Although different theoretical background often leads to different treatment models, in panic disorder and agoraphobia in general the treatment consists of the same components: (1) psychoeducation about the nature and causes of panic disorder and agoraphobia, (2) cognitive restructuring, which targets the negative cognitions associated with panic, and (3) exposure to interoceptive bodily sensations and agoraphobic situations. Sometimes, this program is completed with breathing skills training and relaxation but in clinical practice these have been largely abandoned given findings that they do not enhance outcome (Schmidt et al., 2000).

Dismantling studies of the various components of CBT for panic disorder and agoraphobia have had inconsistent findings (Craske and Barlow, 2008). On one hand, it was found that cognitive therapy as a component may be effective (Williams and Falbo, 1996) even when it is conducted without exposure and other behavioral components (Salkovskis et al., 1991). On the other hand, it was found that cognitive therapy does not have an additional value above exposure in

patients with agoraphobia (Craske et al., 1997; Ost et al., 2004). In more recent research, it was found that exposure-based interventions are usually superior to cognitive interventions in agoraphobia (Moscovitch, 2009; Sanchez-Meca et al., 2010).

Psychoeducation

The first phase of treatment for panic disorder and/or agoraphobia usually includes psychoeducation about the nature and causes of panic disorder and agoraphobia. This information usually consists of making a more detailed and clear distinction between anxiety and panic. Further, the relationship between experiencing anxiety, panic-related bodily symptoms, and cognitions is explained (e.g., the vicious circle of panic, (Craske and Barlow, 2008)). Detailed analyses of recent panic attacks often help the patient to become aware of these relationships. If appropriate, the relationship with agoraphobic avoidance behavior is further explored in collaboration with the patient. To obtain objective information in treatment sessions, it is important to let the patient record their panic attacks and the correlating symptoms, feelings, and thoughts.

Exposure *in vivo*

Marks (1978) has argued that exposure therapy works through emotional habituation. Habituation is defined as a decrease in fear reactions in response to repeated exposure to the feared stimulus. In panic disorder and agoraphobia, exposure targets fear of bodily sensations (interoceptive exposure) and agoraphobic situations (Emmelkamp and Powers, 2010; Meuret et al., 2012).

Meta-analyses and reviews of exposure for panic disorder and agoraphobia (Mitte, 2005; Sanchez-Meca et al., 2010) show that exposure *in vivo* has a substantial effect size for reducing agoraphobic symptoms. Additionally, exposure-based interventions (including virtual reality exposure, Meyerbröker, 2014) show strong effect sizes in reducing agoraphobic avoidance behavior (Meyerbroeker et al., 2013; Moscovitch, 2009). Interestingly, therapist guidance during exposures appears important (Gloster et al., 2011). This large Randomized Control Trial showed that guided exposure *in vivo* was more effective than exposure without therapist guidance in reducing the number of panic attacks, avoidance behavior, and improvement in global functioning.

Interoceptive Exposure

Because individuals with panic-related symptoms usually misinterpret their bodily sensations and therefore panic even worse, one important aspect in the treatment of panic disorder is interoceptive exposure. The aim of the exposure is twofold: first, one can tolerate uncomfortable bodily sensations and second that these symptoms will decrease over time without any intervention. Thus, the patient will learn to tolerate the symptoms without misinterpreting the symptoms as resulting in the feared consequences. Additionally, the patient can compare the provoked paniclike symptoms and compare them to the recently, nonprovoked symptoms, and panic attacks.

Cognitive Restructuring

Cognitive restructuring is often introduced in combination with the recording of the panic attacks over the early therapy sessions. The purpose of cognitive restructuring is to investigate together with the patient what thoughts and possible misinterpretations they experience along with panic attacks. Often, these thoughts or misinterpretations come along with negative emotions, which in turn can strengthen the symptoms (e.g., vicious circle of panic). By having a closer look together with the therapist at these thoughts and emotions, the patient might become more aware of certain thoughts. These thoughts – automatic thoughts – are important in panic disorder because they often generate negative behavior due to the misinterpretation of the symptoms. When patients have identified these automatic thoughts, they can be challenged with more rational alternatives.

Relaxation and Breathing Training

Often, relaxation and/or breathing training is added to the treatment of panic disorder. The purpose is to help the patient to relax more easily when a panic attack is occurring. However, research shows that the above-mentioned treatment components are usually more effective than relaxation training (Barlow et al., 1989) and results are maintained at 2-year follow-up (Craske et al., 1991). The breathing training is often offered but not actively practiced in therapy sessions.

Pharmacological Treatment

Generally, selective serotonin reuptake inhibitors are the medication of choice for panic disorder and agoraphobia as indicated by placebo-controlled randomized clinical trials (Roy-Byrne and Cowley, 2002). In meta-analyses, medium to large effect sizes are reported when compared to Placebo (Mitte, 2005; Bakker et al., 2002). The use of benzodiazepines is not recommended because of their physiological dependence and withdrawal (Roy-Byrne and Cowley, 2002) and because of only temporary symptom remedy (for a review about the use of benzodiazepines in combination with psychotherapy see Watanabe et al., 2007).

Recently, it has been questioned whether the combination of pharmacological treatment with psychological treatment has an additional value (Fernandez-Arias et al., 2013). It was found that in the long run, patients profited more from empirically supported psychological treatment than from psychological treatment in combination with pharmacological therapy.

Future Directions

Although we discussed some findings on potential mediators and moderators of treatment outcome, future studies should increase our confidence in more specific targets. Further, new analysis strategies offer more powerful methods to test such mediation targets (Smits et al., 2012). For example, Kazdin (2007) outlined seven conditions to establish mediation including (1) the selection of mediators must be guided by theory; (2) treatment studies must include measures of potential mediators; (3) the timeline of the proposed mediator

and outcome must be established; (4) studies must assess more than one mediator; (5) studies must use designs that can evaluate mediators; (6) different types of studies must provide converging evidence; and (7) treatment studies must be complemented by experiments that manipulate the mediator to provide converging evidence. As more researchers use these more stringent criteria, our understanding of mediators and moderators should improve.

Future research will also likely include transdiagnostic models of psychology focusing on cognitive endophenotypes of psychopathology from an integrative cognitive psychology perspective (Emmelkamp et al., 2014). For example, emotion dysregulation (Hofmann et al., 2012) and rumination or repetitive thinking (Ehring and Watkins, 2008) are implicated across various mood and anxiety disorders. Such findings have led to transdiagnostic manualized protocols. Initial results are promising. Two open clinical trials of a transdiagnostic treatment suggest that this approach can distil common strategies and enhance the effectiveness by targeting core affective 'higher order' components, which results in substantial clinical improvement in primary and secondary disorders (Ellard et al., 2010). These findings were extended by Farchione and colleagues (Farchione et al., 2012), who treated 38 patients with a unified protocol consisting of 5 modules, which targeted key aspects of emotional processing and regulation of emotional experiences: (1) increasing present-focused emotion awareness, (2) increasing cognitive flexibility, (3) identifying and preventing patterns of emotion avoidance, (4) increasing awareness and tolerance of emotion-related physical sensations, and (5) interoceptive and situation-based emotion focused exposure (Farchione et al., 2012).

Clinical Implications

It is important to translate research into clinically meaningful working protocols. As mentioned above, recent approaches to more transdiagnostic models of psychopathology are a promising first step into clinically meaningful results. If, for example, multiple diagnosis and specific treatment protocols can be combined, this can result in more fruitful and effective treatment planning. If this approach proves to be successful in emotional disorders, it might promote dissemination of evidence-based treatments. Another important aspect is the need for more effective studies wherein not all comorbidities are excluded. This makes studies more representative for clinical practice and might help to clarify why some treatments work for some individuals but not for others.

Paralawyers: Other Legal Occupations

Herbert M Kritzer, University of Minnesota Law School, Minneapolis, MN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Although legal services are thought to be the domain of lawyers, those employed in many other occupations do law-related work, some incidental to other work and some, here called para-lawyers, as the sole focus of what they do. Para-lawyers have long existed, but they are becoming more visible as providers of legal services with the development of systems for licensing and regulating para-lawyers. Research shows that para-lawyers can be effective providers of a range of legal services, and that under some circumstances they can be more effective than fully qualified lawyers. Understanding the phenomenon of para-lawyers raises issues related to closure, deprofessionalization, postprofessionalism, and gender.

Definition

Para-lawyers are persons who perform 'law work' although they are not themselves licensed as lawyers. 'Law work' refers to those activities requiring at least some of the specialized legal knowledge and skill of the type associated with the work of lawyers. Thus, para-lawyers are 'law workers' who lack the full credentials and/or status associated with the legal profession but who provide services that draw on expertise in law and/or legal processes. This negative definition reflects the complexity of defining the practice of law and what constitutes membership in a legal *profession*.

Drawing the line between lawyers and para-lawyers varies from country to country because of variations in the nature of legal tasks within different legal systems and how those tasks are assigned to particular occupations. In many countries, the exact line is not clear. In some countries, the term most equivalent to 'lawyer' is customarily applied to an occupation engaged in a very narrow range of activities, while there are other occupations requiring substantial formal legal training that perform work that elsewhere would be the exclusive domain of the legal profession. Deciding whether to include such occupations under the label of 'lawyers' or 'para-lawyers' requires drawing arbitrary lines. One example is the legal occupation of notary as it exists in many civil law countries (Malavet, 1996). Historically, the occupation of notary arose to provide a neutral person who could be trusted to draw up fair contracts to be executed by one or more persons unable to read or write; today, notaries continue to play a role in the drawing up of and execution of contracts, and they apply specialized legal knowledge related to those activities. If the notary's tasks involve anything more than ministerial functions such as witnessing the execution of contracts, as is the role of the notary in the United States, it is arbitrary whether the notary is deemed to be part of the legal profession or is instead categorized as a para-lawyer, although some distinctions might be made based on the education and training requirements to become a notary.

In addition to problems of drawing a line between lawyers and para-lawyers, it is difficult to draw a line between para-lawyers and some 'nonlaw' occupations because many nonlaw occupations require the use of some very specific legal knowledge, typically applied in a very routine way. Examples include drawing up contracts for routine property transactions (in the United States typically done by real estate sales agents), drawing up routine loan contracts (done by bank officials), settling tort-based injury claims (done by nonlawyer representatives of insurance companies), or advising on estate or tax issues (done by financial advisors and accountants). In one sense, all of these occupations could be labeled para-lawyers; for some of the occupations the para-lawyer work is only a part of their activities (e.g., real estate sales agents) while for others (e.g., insurance claims representatives) it is the vast bulk of their work.

In some countries (e.g., Japan), rights of audience in court might serve as a clear demarcation between lawyers and nonlawyers. However, in other countries there are branches of the legal profession that have no rights of audience (e.g., notaries in civil law countries) and in others some para-lawyers have been granted rights of audience in court (e.g., England for legal executives and Ontario for licensed paralegals). In fact, in England it is now possible for 'chartered legal executives' to become District Judges (the lowest level of professional judges in England, once called 'stipendiary magistrates'). Note here the reference to 'rights of audience in courts'; in many countries nonlawyers may represent parties before administrative tribunals and undertake various types of work not involving litigation. In recent years, at least two American states (California and Washington) have established procedures for licensing nonlawyers to assist clients in preparing a range of legal documents. In many jurisdictions there is no licensing procedure, and a range of legal work can be done legally by anyone who chooses to offer the service.

Finally, there is no recognized standard of education or specialized training to become a para-lawyer. Although there are training courses for occupations variously labeled 'paralegal,' 'legal assistant,' or 'legal executive,' these courses do not provide formal qualifications, and most people enter such occupations without any formalized training (Johnstone and Wenglinsky, 1985: pp. 121–123). Other kinds of para-lawyer occupations involve the application of knowledge learned in some other role; examples include former police officers representing traffic offenders in Ontario (including those charged with serious offenses such as driving while intoxicated), former Internal Revenue Service (IRS) auditors representing or assisting taxpayers in disputes with the IRS in the United States, former insurance company claims inspectors or adjusters

representing injury claimants in England, and legal secretaries who take on increasing responsibilities to the point where they are engaged more in law work than in secretarial work. Thus there is no clear way to decide whether a person offering a particular set of services, or engaged in a particular set of tasks, should be classified as a para-lawyer; nor is the term 'para-lawyer' in common use in a way that would allow for self-identification.

Empirical and Theoretical Issues

Even with these definitional and boundary problems, the concept of para-lawyers, and para-professionals more generally, is useful theoretically and important for practical purposes. It raises the issues of how law work is and should be structured, and what qualifications are needed to be effective in law work. In addition, there are three other lines of theoretical inquiry that are important vis-à-vis para-lawyers: achieving profession or 'closure,' 'deprofessionalization,' and the gendering of occupations.

Structure of Law Work

Law work readily divides along at least three dimensions: institutional setting; legal advice vs legal assistance (preparing documents, advocacy before a neutral third-party, negotiating with another party); and routine vs nonroutine tasks. The degree to which para-lawyers have in the past, and are today, providing legal services varies along these dimensions. As one moves among institutional settings – from office, through tribunal, to lower courts, and finally to the higher courts – the role of para-lawyers tends to decrease. Para-lawyers are most often excluded from law work in upper-level trial and appellate courts, and least often from tasks that can be completed in the privacy of an office. For example, in England, lawyers enjoy a monopoly on representation in the higher courts; in contrast, office-based work generally is not limited to lawyers, nor is representation before administrative tribunals. As noted previously, legal executives in England can now appear in some court proceedings to handle preliminary matters in criminal cases, and licensed paralegals in Ontario can handle small claims litigation, traffic offenses, and minor criminal offenses in lower level courts.

Continuing with the example of England, para-lawyers direct a larger proportion of their effort toward providing advice on legal matters, broadly defined, while lawyers are more likely to engage in active assistance. In part this is because accounting firms and advice bureaus staffed by nonlawyers are major providers of legal advice in England (Baldwin, 1989; Citron, 1989). Similar advice bureaus also exist in New Zealand and in at least some states of Australia. In other countries, it is likely to be the case that para-lawyers are more involved in advice-giving simply because it is less visible, and hence difficult for regulators to limit or otherwise control.

The more that routines can be established to handle a legal task, the more possible it is for someone with very specific training and/or expertise to handle the task, even if it is highly technical. For example, in the United States, appeals of certain types of government benefit claims involve highly technical issues of both regulations and medical assessment. Such cases tend to be handled by specialists, some of whom are lawyers and some of whom are para-lawyers. On the less technical side, there are many legal processes that are routine but require the completion of various kinds of forms; para-lawyers can both identify the forms needed for various processes and assist consumers in the completion of those forms, although increasingly there are online services (e.g., LegalZoom, Nolo, Rocket Lawyer) that can assist consumers with such tasks.

One final issue concerning the structure of legal work and para-lawyers is whether they work as independent service providers or under the supervision of lawyers. Many lawyers employ para-lawyers to complete routine and/or specialized tasks within the lawyers' practices (Johnstone and Wenglinsky, 1985); many legal departments inside organizations employ a mix of lawyers and para-lawyers all under the supervision of senior lawyers (Kelly, 1994: pp. 96–99). Typically, para-lawyers working under the supervision of lawyers is an accepted delegation of responsibility, although there is substantial variation in drawing the line between what a para-lawyer may do and what requires a lawyer. As mentioned earlier, one frequent boundary is the courtroom door: representation in court tends to be limited to lawyers, although that may be less so in the lower courts (the example of Ontario noted previously) and it is changing under both political and economic pressures (the example of para-lawyers handling certain criminal matters in England, and the role of specialized advocates in certain types of cases such as domestic violence).

Effectiveness in Delivery of Legal Services

A key question with regard to the work of para-lawyers is how it compares in quality to the same activities carried out by lawyers. Although lawyers claim that use of para-lawyers raises concerns about poor-quality work, systematic comparisons of the work of lawyers and para-lawyers fail to support this contention (Kritzer, 1998; Moorhead et al., 2003). The extant research demonstrates that para-lawyers can be as effective as lawyers in providing specific legal services. Achieving effectiveness involves a combination of specific knowledge or expertise vis-à-vis substantive law, institutional process, and other actors in the system. Para-lawyers who obtain this combination can achieve levels of effectiveness comparable to that of lawyers, and specialized para-lawyers may be more effective than lawyers lacking one or more of the core elements of knowledge.

The relationship between the service provider and the client can also influence the relative effectiveness of the provider. Specialist para-lawyers who have ongoing relationships with clients may be more effective than even specialist lawyers brought in on an ad hoc basis to handle a specific matter; this reflects the knowledge base created by the ongoing relationship. The payment arrangement between service provider and client may also make a difference. One study (Kritzer, 1998: pp. 111–149) that found specialist lawyers to be more effective than specialist para-lawyers in a particular area attributed the difference in significant part to the lawyers being paid on a no-win, no-fee basis while the para-lawyers' compensation was unaffected by the outcome of specific cases. Another study found little or no difference between lawyers and para-lawyers, and in that study the lack of difference may have been due to different

compensation models for lawyers and para-lawyers that effectively allowed the para-lawyers to devote more time to an individual matter than could a solicitor (Moorhead et al., 2003).

Achieving Profession, Deprofessionalization, and Postprofessionalism

One issue for para-lawyers has been achieving recognition as a distinct profession. Typically this is reflected in efforts to establish a system of licensing that is somewhat under the control of the profession itself. Such a system imbues the occupation with status it previously lacked while also creating what sociologists of the professions have typically labeled 'closure' (Abel, 1989: pp. 20–24; Witz, 1992). Para-lawyers have had mixed success in their efforts to achieve closure. Most successful have been the English legal executives who are now regulated by their own body, the Institute of Legal Executives. Ontario paralegals may have achieved closure, but they are subject to regulation by the Law Society of Upper Canada, which has long been the regulatory authority for lawyers in Ontario. The legal document assistants in California who register with and are regulated by the state Department of Consumer Affairs have achieved an element of closure but not in a form associated with a professional status. Importantly, both the Ontario licensing scheme and the California system for what amounts to licensing legal document assistants (and which includes a second group called unlawful detainer assistants who handle eviction proceedings) was initiated by members of the legal profession rather than by members of the occupational group subject to the regulation.

'Deprofessionalization' refers to the shift from professional to nonprofessional status. Professional status is conferred on those occupations that maintain a monopoly over a theoretical base of knowledge, have expectation of autonomy in regulation and day-to-day work, and promote a belief in the professional having a service ethos. Deprofessionalization refers to the loss of these supposedly unique occupational qualities (Haug, 1973; Rothman, 1984). Nonprofessionals such as para-lawyers increasingly do work once the province of professionals. Deprofessionalization reflects several specific developments.

First is the combination of the rationalization of knowledge, the rationalization of tasks employing knowledge, and the growth of tools to assist in applying knowledge. The more that tasks can be compartmentalized and the more that knowledge-based tools can be applied, the easier it is to assign the task to a person with limited, specific expertise. The result is the de-skilling of knowledge-based occupations.

A second development is the loss of governmental support for restrictions limiting the role of para-lawyers. In England, solicitors held a monopoly on handling land transfers for many years, but these tasks are now open to licensed nonlawyer specialists. In the United States, limitations have been under attack politically at both the national and state level (Commission on Nonlawyer Practice, 1995).

The third development is the increasing bureaucratization of legal service delivery. Once organizational structures become established, there is a drive to rationalize, compartmentalize, and reduce costs. Bureaucratic structures also provide means for supervision and control, which both creates tensions for professionals expecting autonomy and provides a setting to monitor the work of para-lawyers.

A frequent claim by lawyers seeking to secure and maintain restriction on the delivery of legal services is that opening such work to para-lawyers and other nonlawyers jeopardizes the interest of clients both because of lack of competence and the absence of the stringent ethical norms of the professional. As noted in the previous section, systematic research in several countries has failed to support this claim (Kritzer, 1998; Moorhead et al., 2003). The loss of this argument combined with drives to contain costs through broadening options in service-oriented markets pushes toward less and less control of 'professional' services.

The concept of deprofessionalization suggests the loss of something. An alternative concept, 'postprofessionalism' (Kritzer, 1999), reflects most of the same elements but sees the opening of legal and other professional services to para-professionals, such as para-lawyers, as part of a natural development. Postprofessionalism builds on the growth of technological tools to access knowledge previously the exclusive realm of persons with professional-level training (Susskind, 1996, 2008). These developments parallel the industrial revolution, when the rationalization of tasks and the development of machines led to the shift from crafts-based production to factory-based production. Postprofessionalism captures the image of a similar shift for people who work with their heads rather than their hands: rationalization of knowledge combined with information technology tools make it possible to produce services using workers with lower levels of training and knowledge.

Gendering of Occupations

A final issue in the analysis of para-lawyers relates to the gendered nature of occupations. Historically, professions have been male-dominated while many para-professions have been female-dominated. Within law-work, women were largely excluded from the professional ranks until about 1970. In the early twentieth century, some of the American states formally excluded women from the bar; even where they were not excluded, women were often confined to roles such as legal secretary even if they had the formal credentials of a law degree. Since 1970, most countries have witnessed the opening of the legal profession to women, and the number of women who practice as lawyers has increased sharply.

Nonetheless, para-lawyer roles tend to be dominated by women; this is particularly true of para-lawyer positions that are specifically subordinate to lawyers (Johnstone and Wenglinsky, 1985: p. 69). Even for those para-lawyer positions that function independently of lawyers, the gender composition may limit the likelihood of achieving some sort of full professional status as long as they are seen as in competition with the existing legal profession (Hearn, 1982). At the same time, efforts to increase occupational status may lead to certain kinds of 'closure' strategies that bear a resemblance to those employed by lawyers: formal licensing, testing requirements, educational qualifications, and so forth (Witz, 1992; Johnstone and Wenglinsky, 1985: pp. 165–166). Whether such efforts ultimately improve status or lock in gendered distinctions is an important theoretical and empirical issue.

A final gender-related issue concerns the professional roles assumed by many of the increasing number of women in the legal profession. A common observation in the literature on the struggles of women to achieve status and economic parity with men in the legal profession is that women lawyers are disproportionately to be found in law-work positions that are themselves in some sense gendered (e.g., family law practice, as employees rather than as principals, etc.). In some ways, the professional roles occupied by many women lawyers are closer to those of para-lawyers than to the traditional image of the work of male lawyers (Sommerlad and Sanderson, 1998). This development may lead to a blurring of lines between lawyers and para-lawyers while preserving patriarchical status structures in the workplace.

Future Research and Theory

As theoretical and empirical concepts, para-lawyers (and para-professionals more generally) are underdeveloped. Current dynamics in the changing occupational structures, such as postprofessionalism, suggest that the para-lawyers should become increasingly important in the study of law work and in the delivery of legal services. The relationship of para-lawyers to the increasing role of information technology is one avenue of potential theory development and research; a second is the economics of service delivery; and a third potential area is in the relationship of para-lawyer occupations to broader patterns of changing social structures, particularly the changing impact of gender on social structure.

Parallel Relationships

Catherine Hakim, Civitas, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Parallel relationships encompass many types of extramarital sexual encounters and relationships, including flings, hookups, casual sex, mistresses, courtesans, concubines, swinging, sex parties, and long-term romantic or sexual relationships. Sex surveys suggest a rising trend in such recreational sexual activity, prompted by the contraceptive revolution of the 1960s. The incidence of extramarital affairs also rises with duration of the primary relationship, as boredom sets in. Parallel relationships may overlap with use of commercial sexual services, and are more common within highly educated and high-status groups.

Sex researchers in Scandinavia adopted the term parallel relationships to cover sexual or romantic liaisons, whether brief or long lasting, concurrent with any primary sexual or romantic relationship (Kontula, 2009). The term thus encompasses sexual relationships that are variously called hookups, flings, one-night encounters, swinging, casual sex, and extramarital affairs of any duration. Strictly speaking, hookups with men and women who sell sexual services should also be included, especially as these may become ongoing relationships with regular clients. The dividing line between professional and nonprofessional sexual liaisons that was so important in previous centuries in the Western world is fading rapidly in the twenty-first century. Just one example is the relationship between the 'sugar daddy' (or mommy) and the young, attractive girlfriend (or boyfriend) who they support financially (Croydon, 2011). However, the formal sale and purchase of sexual services, whether gay or heterosexual, have distinctive features, are criminalized in some countries (such as the USA), not in others (such as most of Europe and New Zealand), or is tolerated even when strictly unlawful (as in Thailand), so it is covered separately in this article.

It is essential to note that paid sexual services and unpaid casual sexual relationships (including affairs) are functional alternatives that substitute for each other and cannot always be differentiated (Hakim, 2011: 150–152). People who report two or more sexual partners in sex surveys may be referring to liaisons in the commercial sex industry as well as to ongoing lovers. By eliminating the risk of unwanted pregnancies, the contraceptive revolution of the mid-1960s made premarital and nonmarital sexual relationships less problematic. This opened the door to an expansion of recreational sex for people of all ages, whether married or not, an option that had previously been restricted to royalty and the aristocracy, people wealthy enough to cope with the financial costs of any consequential offspring. The defining characteristic of parallel relationships, like commercial sexual services, is a primary focus on recreational sex, or fantasies of recreational sex, and related entertainments, in contrast to the very different long-term goals of marriage and cohabitation, which usually include raising children and a common lifestyle.

The most immediate effect of the introduction of reliable contraception (the pill, intrauterine device, and sterilization) in the 1960s was a rapid expansion of premarital sex among young single people, often considered shocking at the time. The second, less visible, and much slower consequence was an increase in extramarital relationships, swinging, flings, and casual sex among people of all ages – what the French call *aventures* and *petites aventures*. The third effect was a decline in male demand for commercial sexual services (and a consequential fall in the prices for such services), as men switched to using nonprofessional sexual liaisons as a substitute for commercial services (Levitt and Dubner, 2009: 29–31). It is notable that the official report on the 1966 Swedish national sex survey, in line with comments by Swedish social scientists, takes it for granted that men can get as much sex as they want from nonprofessionals on the 'normal sex market' of nonmarital sex (Lewin, 2000; Hakim, 2011: 148–149). It thus makes sense to think of a wider sex market that includes amateurs as well as professionals, marital and nonmarital liaisons, whether heterosexual or homosexual – even if notional 'prices' and values vary between sections of the market due to scarcity and demand (Laumann et al., 1994: 11–12; Baumeister and Vohs, 2004; Hakim, 2011: 194–200).

The focus here is on extramarital sexual and/or romantic liaisons among people who are married or in committed relationships. The article focuses on modern societies where monogamy, or serial monogamy, is the norm, and on 'vanilla' sex, excluding the special features of minority sexual entertainments, clubs, and communities such as Bondage Domination Sadism Masochism (BDSM) and other sexual variations. For simplicity, longer-term relationships are labeled as marriages.

The statistical and survey evidence quoted is taken from the nationally representative sex surveys of the 1980–2010 period around the world that are reviewed by Hakim (2011: 31–61, 2012: 33–42). Case study evidence from around the globe is provided by Druckerman (2007).

Incidence and Trends

The incidence of affairs varies between countries and cultures, men and women, and high-libido and ordinary people. But there is no doubt at all that the incidence of parallel relationships is increasing in many modern societies, even if comprehensive and reliable statistics are not always available. Statistics for the various types of parallel relationship generally show an upward trend in the proportions reporting *ever* having an affair or fling, or reporting such activity in *the last year*, or some other

specified period. However, case studies and qualitative research indicate that depth interviews can double admissions of affairs, from 30 to 60%, in countries where they are considered deviant (Hakim, 2012: 18).

Between 1990 and 2000, the proportion of men and women admitting to extramarital affairs doubled in Britain, and then rose again in the next decade. The upward trend was unmistakable, even if there was some increase in willingness to report such activity, which is usually carefully concealed. Nonetheless, the incidence remains low compared to other European countries. In Britain, among people married for over 5 years, 10% of men and 5% of women admit to ever having an affair. In the USA and Britain, across all age groups from 18 to 60 years, 2% of wives and 5% of husbands admit to an affair in the last year (Hakim, 2012: 18).

The duration of a relationship is relevant: percentages rise with increasing durations of marriage (and hence with age). American, French, and English surveys all confirm that the incidence of extramarital affairs and flings rises the longer people have been married, from close to zero in the first 3 years of a relationship, the 'honeymoon' phase, to over 20% (among French men) and around 14% (among French women) after 5 years of marriage. This pattern is observed in all age groups, in both first and second marriages (Hakim, 2011: 126).

In some countries, surveys report the incidence of two or more sexual partners – in the last year, the last 5 years, or ever – without trying to specify the nature of the relationships. These statistics inevitably *under*state the incidence of parallel relationships, because a relatively high proportion of marriages is celibate, or virtually sexless, especially when spouses are over 40 years of age (Hakim, 2011: 41–44, 2012: 65–70). Men who report a single sexual partner may be referring to a mistress or casual hookup rather than their wife. This is clear from the fact that wives are generally twice as likely as husbands to report their marriage has been celibate – for the last month, the last year, last 5 years, or whatever period is used. Many husbands resolve the problem of a sexless marriage through affairs, the sex industry, or casual hookups.

The American 1992 sex survey (Laumann et al., 1994) did identify spouses in celibate marriages who had lovers: 15% of husbands and 8% of wives. Reports of affairs are broadly consistent across surveys in America: one-quarter of husbands and 15% of wives report ever having an affair. The proportions rise with age: one-fifth of men with 30–40 years of age vs two-fifths of men with 50–60 years of age ever had another sex partner. These figures suggest that about half of all affairs occur within celibate marriages. The survey also reports people who had two or more partners in the last year after controlling for age, marital status, race, education, and other factors, to arrive at a standardized average for people admitting to more than two partners (19% for men and 13% for women), or more than five partners (4% for men and 2% for women). Everything points to men being twice as likely as women to have several sexual partners during marriage, and even more so before or after marriage (Laumann et al., 1994: 210–217).

A common reaction to these figures is to say they must be unrealistic, as male and female sexual activity must balance out, overall. No, it does not – for three reasons. First, men and women who sell sexual services (as a full-time or part-time activity) do not participate in sex surveys, as these are clearly not addressed to their situation, and participation is voluntary. Since the vast majority of sex workers are females, this removes women with high numbers of partners from survey results. Furthermore, the vast majority of male sex workers are selling services to gay men, not women, so they are reported as partners by other men, not by female clients. Second, sexual markets are not restricted by national borders, unlike sex surveys. Men who have affairs, or purchase sexual services, may do so outside their own country, while away on business trips abroad or during sex tourism holidays in places with more tolerant policies such as Thailand or Spain. For example, Swedish surveys show that 80% of men who buy sexual services do so outside Sweden (Lewin, 2000; Hakim, 2011: 149). The policy of criminalizing such activities in Sweden leads to the industry being outsourced to foreign countries. Third, heterosexuals invariably overlook the impact of the gay community on overall sex statistics. All studies show that gay men report the highest numbers of partners, far above the maximum numbers reported by heterosexual men. In gay sex, both partners are male; no females are involved. These three factors together far outweigh any impact of men's tendency to exaggerate and women's tendency to minimize reports of sex partners.

Parallel relationships are more common in Europe and other countries (Druckerman, 2007; Hakim, 2012: 13–21). In Italy, one-quarter of men and one in eight women admit at least one affair at some time, with the highest incidence among graduates. Less than half of Italians (two in five) regard affairs as unacceptable. In Spain, half of all husbands and one-quarter of all wives admit to affairs. Affairs are not always successfully concealed: one in ten married people in Spain are aware that *both* spouses have had an affair. Attitudes are consistent: one-quarter of Spaniards do not regard sexual fidelity as fundamentally important, and fear of discovery is admitted to be the main barrier to engaging in such dalliances. Clearly, the values promoted by the Catholic Church are not accepted unquestioningly, and many Spaniards must be using effective contraception. In France, it is estimated that one-quarter of adults are having affairs at any one time. Attitudes in France are most permissive, as affairs are taken for granted as something that happens throughout life, if you are lucky. Two-thirds of French men and half of French women accept that sexual attraction inevitably leads to intimacy. Two-fifths of the French do not equate love with sexual fidelity, which is another way of saying that they continue to love their spouse even when seeing a lover. The incidence of parallel relationships seems to be highest in Finland, where the surveys do not bother to count flings and one-night encounters. Here, half of all men and one-third of all women have had at least one serious affair while married. A minority of men report over 10 such relationships. Sweden's reputation as the land of 'free love' must refer to premarital sexual activity rather than affairs, as only one-fifth of women and two-fifths of men have ever had an affair while living with a primary partner. In Japan, the 'love hotels' of big cities and country spa inns are used by married people and their lovers as much as by courting singles seeking privacy. Even in straight-laced China, one in ten husbands and one in twenty wives admit to at least one affair (Hakim, 2012).

Concurrent sexual partners are generally far more common among young people who are not yet married. However, most

sex surveys notice that there is a small minority of sexual 'superactives', who have an early sexual debut, numerous partners, and wide sexual experience. This group is dominated by men – gay, heterosexual, or both – who espouse a distinctive ethos of sexual exploration and adventure. For example, the Swedish survey found men were three times more likely to define the ideal sexual lifestyle as having a variety of concurrent lovers: 20% vs 6% of women (Lewin, 2000).

Several features of modern societies are conducive to the growth of affairs and flings, even in cultures that are firmly opposed to the idea, such as Britain and the USA, where 80 and 90%, respectively condemn infidelity (Hakim, 2012). With life expectancy increased to around 80 years in Western Europe, marriages can potentially last for 60 years or more today, whereas they lasted around 20 years on average in 1900. Boredom with the regular partner is an important factor in affairs; the posthoneymoon phase is now very long indeed. Another factor is the increasing secularization of cultures and values. The steady rise in civil (nonreligious) marriages is relevant: no 'vows' or promises are made, unless the couple actively chooses to include some, and they can specify their own norms and rules to suit themselves. A factor that influences some people is awareness of the hedonistic values of sexual adventure and exploration that apply in many parts of the gay community. Many gay men in long-term relationships still enjoy flings and casual sex with other men, sometimes in explicitly 'open' relationships. Other people look enviously at the sexual freedoms enjoyed by young singles, including their own children. A sexualized visual culture may have a diffuse impact on attitudes and behavior: advertising, pop videos, films, and TV display nudity and sexuality more frequently today than in the twentieth century, awakening or reinforcing libidos. The expansion of foreign travel and holidays is another factor, increasing awareness of the more tolerant attitudes toward affairs and flings in Southern Europe, for example. People who travel a lot also find it easier to have affairs in other locations, away from home and the constraints of normal life. Rising levels of education and greater affluence in a society are contributing factors, as all surveys show the incidence of nonmarital sexual liaisons to be highest in highly educated and high-income groups – because they have more relaxed and cosmopolitan attitudes, or because they can afford the inevitable costs.

Urbanization is another important macrolevel factor, as it increases the feasibility of affairs. Couples can meet more discreetly in cities and metropolitan areas than in small closed rural communities where everyone knows everyone else's activities, and gossip is a major form of social control. Urban areas increase the diversity of people encountered in workplaces, leisure centers, and other public places, and offer greater anonymity. Finally, internet dating and the rising number of specialized web sites catering for married dating facilitate meetings between like-minded people and fuels the expansion of what Hakim (2012) terms *playfairs*.

Another invisible but important factor may be the degree of multiculturalism in the local environment, as well as its size. For example, some 300 languages are spoken in London, England, making it the most multiethnic and multicultural city in the world. This type of cosmopolitan environment reinforces the idea of cultural relativism, and promotes the idea that you can step outside the norms of your own community by engaging with someone in a different community – a kind of 'virtual' cultural holiday. However, there is also a high incidence of affairs in culturally homogenous societies where extramarital liaisons are widely tolerated, so long as they remain discreet – such as France, Italy, or Japan.

Since 2000, there has been a proliferation of dating Web sites dedicated to married people seeking casual sex and affairs – in the USA, Britain, Scandinavia, and elsewhere. These Web sites offer a potentially global service. For example, a manager in Hong Kong who will be visiting London or New York on business can search Web sites for women interested in meeting him for a dinner date, and perhaps more. A professional in New York traveling to Paris for a meeting can search for potential partners in that city.

Typically, such Web sites boast that they are among the largest and most successful in their field, with more than 500 000 members often claimed. Many imply that they have broadly equal numbers of male and female subscribers – a claim that is completely implausible according to one study (Hakim, 2012). Typically, men pay subscription fees to use the service (to send and receive messages) whereas women pay nothing at all – in contrast to singles dating Web sites where both parties pay fees. This is a strong indicator that men vastly outnumber women. Hakim (2012) estimates that men outnumber women by at least 10 to 1, possibly 15 to 1, on these specialized Web sites. This illustrates the sex differential in interest in parallel relationships and recreational sex, and is consistent with the results of sex surveys.

The proliferation of married dating Web sites since 2000 reflects and facilitates increasing interest and activity in parallel relationships. Although such dating Web sites do not cost much to run, and rely on standard singles dating software, advertising can be costly, especially as normal advertising channels are often closed to such 'deviant' enterprises. Web sites that do not attract enough customers to become profitable close down fairly quickly. At least one dating Web site switched from supporting singles dating to focus on married dating instead because the niche market was more profitable.

Parallel relationships take three distinct forms: the traditional kept mistress; playfairs and flings; and the more 'democratic' modern swinging and sex parties. The social element declines sharply from the first to the last type.

The Kept Mistress

Throughout history, the mistress and concubine has been an indicator of status and wealth, just as a large number of wives remains a status symbol in countries where polygamy is still practiced – such as Nigeria. Chinese emperors had hundreds of concubines. French kings often had an official mistress (*maitresse en titre*), usually French and freely chosen, who was generally more popular than the official wife, who was inevitably a foreign princess chosen for political reasons. The most famous was Madame de Pompadour, the long-lasting mistress of King Louis XV. Such mistresses were invariably married women, hence respectable ladies. Old traditions persist in new forms. President Francois Mitterand had a long-lasting mistress who was almost a second wife, with a daughter raised in secret.

French law protects the privacy of everyone, including public figures, so the media did not dare discuss the matter until after Mitterand's death.

No statistics are available on the numbers of long-term mistresses, whether financially independent, or in receipt of financial support in one form or another. In some countries, such as Brazil, discreet 'sugar-daddy' arrangements between affluent (and possibly older) men and attractive young women are not stigmatized (Hakim, 2011: 198). There are now specialist dating Web sites in the USA and Britain for 'sugar-daddy' men and attractive young women, many of them students in higher education with debts to pay off. Typically, these relationships are short-lived, lasting for 6 months or so. The global reach of Web sites means that such arrangements are often cross-national in scope. A first-person account of such relationships shows that most if not all the women in question are highly intelligent, well-educated, autonomous, ambitious as well as attractive people (Croydon, 2011). The average age of the successful sugar daddy is around 40–50 years. Many are single men who are dedicated to their careers or business; they want female company at certain times, but choose to avoid the permanent encumbrance of a wife and (potentially) children. Others are older men seeking an attractive younger mistress.

Relationships that develop within a single country have the potential to be longer-lived, especially when they involve a married man and an unmarried woman, who effectively provides a second home as well as sexual entertainment. This type of relationship is unbalanced and potentially exploitative, in contrast to affairs where both partners benefit from the security of marriage (Hakim, 2012).

First-person accounts by modern mistresses in Europe range from those that take a perverse pride in an emotionally dependent secret relationship that confers no financial or social benefits whatsoever on the woman and restricts her social life (Griffin, 1999) at one extreme, to those that rage against the injustice of an exploitative relationship, even when the mistress has received substantial financial and other benefits from her wealthy lover (Symonds, 2007) – with every shade in between.

In the past, the mistress and the courtesan might have similar social status and problems of stigmatization, as illustrated by the Russian novel *Anna Karenina*, and the *grandes horizontales* (courtesans) of the French *Belle Epoque*. These arrangements have become rarer in the Western world, being replaced by playfairs and flings. They are sometimes revived by rising affluence. For example, Hong Kong businessmen who travel regularly to mainland China often maintain a mistress in the Chinese cities they visit, in order to enjoy home comforts while traveling (Druckerman, 2007: 251–270). In China, corruption scandals in big cities occasionally reveal officials with dozens of mistresses.

Playfairs and Flings

What Hakim (2012) terms playfairs and flings are nonmarital, or extramarital relationships of relatively short duration, normally shorter than the relationship with a mistress, and with less financial support. Playfairs may last weeks, months, or (rarely) years.

Historically, nonmarital sex was condemned because of the risk of pregnancy. For an unmarried woman, an illegitimate child represented a major financial burden and ruined her chances of marriage and respectability. Married women could avoid such problems (unless the lover was of a different race, which might be reflected in the baby's appearance). But they would be condemned for duping their husband into supporting another man's child. Men avoided these problems, and could engage in affairs with a lighter heart and even irresponsibility. After modern contraception broke the link between sexuality and fertility, affairs and flings became technically unproblematic. However, modern morality has yet to adapt to the new situation, especially in Puritan Christian cultures. In some countries, the old values became institutionalized in concepts of love, trust, and betrayal that insist on absolute sexual fidelity. Most surveys suggest that the AIDS crisis of the 1980s temporarily reinforced attitudes of disapproval and intolerance everywhere, due to the new health risks.

Two distinct cultures can be identified as regards the theory and practice of playfairs and flings. In Puritan Anglo-Saxon countries, such as the USA and Britain, affairs are widely condemned and are less common. In continental European countries such as Italy, Spain, and France, attitudes are more relaxed and tolerant, albeit never unanimously in favor, and affairs are far more common. Cultures where playfairs are accepted also have well-developed conventions regarding their conduct. For example, affairs should be conducted with elegance, courtesy, and great style in order to guarantee that the liaison offers pleasure, entertainment, and enjoyment on all levels. In France, for example, playfairs are almost a work of art, with elegant dinners, regular gifts, well-planned excursions, and weekends away in romantic places such as Venice or Marakesh. In Japan, when a man wishes to terminate an affair, it is customary for him to make a substantial financial parting gift to his lover, as compensation (Druckerman, 2007).

The general pattern is for Puritan countries to have low tolerance for affairs, high divorce rates, and serial monogamy. Countries with high tolerance for affairs tend to have much lower divorce rates and generally long-lasting marriages. In the USA, around half of all marriages end in divorce. In Britain, about one-third of first marriages end in divorce. Although divorce rates rose in Catholic countries after divorce became legalized through the civil courts, they remain much lower, as also in Japan. In effect, there seems to be a choice between serial monogamy and playfairs as alternative routes to achieving variety and novelty within long-term intimate relationships – for those who need it (Hakim, 2012). Either way, sexual fidelity has become a personal choice, not a necessity or an obligation, in secular modern societies.

In Britain, a large study of men and women engaged in extramarital affairs through the new specialized Web sites (Hakim, 2012) found that a wide variety of triggers and catalysts prompted an affair, such as: a partner's illness or unavailability for other reasons; the early death of a friend reminding them of their own mortality; a desire to enjoy (or regain) youthful vitality and sexual excitement; or a desire to experience the youthful hedonism that eluded them due to early marriage. However, the root cause of the majority of affairs was a celibate or sexually starved marriage. This common explanation is corroborated by evidence on celibacy

from national sex surveys and other research showing that men's sex drive is stronger than women's (Baumeister et al., 2001; Hakim, 2011: 31–61, 2012: 65–70).

In Europe and the USA, in the absence of any distorting social constraints, there are no sex differences in sexual interest among young people, up to the age of about 30 years. From then on, women start to lose interest in sex, while men's libido does not diminish. Half of all men over the age of 30 wish they had sex more often in their current relationship, compared to less than one in ten women. From the age of 35 years onward, celibacy increases rapidly among women, but rises very slowly among men (Hakim, 2011: 39–50). In the USA, one-fifth of marriages are sexually inactive. In Britain, among people with 45–59 years of age, one-fifth of married couples have been celibate for the last year, and one in ten have been celibate for 5 years or more.

The celibate character of many marriages is reflected in attitudes. In Britain, two-thirds of people agree that sex is not the most important element in a marriage. Curiously, this is in line with the continental European view that marriage is primarily about investments in children, property, a common lifestyle, values, and friends.

Inevitably, married people who have recourse to sex therapists and marriage counselors are a self-selected unhappy group who identify serious problems with their relationship that potentially lead to separation if not resolved. So the picture of affairs that emerges from books by counselors is typically negative, and differs fundamentally from the picture from wider population samples (Hakim, 2012: 35–42). Men and women using the dating Web sites for married people are typically happily married, and certain that they do not want to change their situation. They are not seeking an excuse to terminate their primary relationship, by 'falling in love' with someone else, or by provoking their spouse's rage at discovering an affair, to prompt a rapid divorce. These successful affairs are labeled *playfairs* by Hakim (2012) to differentiate them from the emotional–romantic liaisons that are both cause and consequence of an unsatisfactory marital relationship.

Paradoxically, men and women using the dating Web sites for married people often express strong family values, especially as regards their responsibilities for their children's well-being and long-term care. Some insist that they have a 'perfect marriage' except for the sharp imbalance between spouses in sexual interest. This leads them into strict procedures to maintain the secrecy of their affairs. In effect, they observe the two fundamental rules of the affair identified in French culture. First, an affair must never be obvious, should always remain discreet, so that the spouse is never embarrassed in any way. Second, affairs should never be conducted close to home, within your neighborhood, workplace, or friendship circle, as this raises the likelihood of accidental exposure and embarrassment.

Some users of the married dating Web sites treat their affairs primarily as sexual adventure. The emphasis is on sexual exploration and sensuality. This group veers toward casual sex and one-off hookups rather than continuing liaisons (Hakim, 2012), although some approach the continuity displayed in the film *Last Tango in Paris*. This type of heterosexual affair is a close parallel to affairs in the gay community, where casual and anonymous sex is far more common, among both partnered and unpartnered men (Weinberg and Williams, 1975). The key difference is that heterosexual affairs are almost invariably concealed; they are not part of an 'open' relationship, even when there is implicit tolerance of occasional flings.

Web sites for playfairs are popular because they facilitate secrecy. They allow people to avoid meeting anyone they might potentially know socially or through their occupation, by excluding people within the same neighborhood or type of business. The Web sites thus operate in the *opposite* way to singles dating, where people mostly choose to meet others who live in the same area, with similar occupations, or similar leisure interests. People on the married dating Web sites *actively exclude* anyone who might be too close to them, for example by avoiding people in their own ethnic community or religious group.

Given the statistics on celibate marriages, it is no surprise that men outnumber women on the Web sites for affairs. Some married men also use singles dating Web sites and singles bars with a view to achieving sexual encounters with young single women. Estimates suggest that around one-third of men on singles dating Web sites are married men 'on the prowl' for extra sex.

Physical and social attractiveness, or what Hakim (2011) terms *erotic capital*, is an important determinant of men's and women's success in attracting and keeping partners, and this is especially true of affairs (Hakim, 2011: 194–198, 2012). Long-term relationships often include investments in children, property, joint friends, common interests, and lifestyle. This sort of glue is missing in short-term liaisons, so erotic capital and entertainment are highlighted. Attractive people have an earlier sexual debut, and acquire more sexual experience. In Europe, they attract more sexual partners. On the specialized Web sites, people with high erotic capital attract more interest, have greater choice of partner, and can impose their own conditions for any liaison, including expectations of entertainment, gifts, and even financial support. Here again, there is an overlap between the affair, the 'sugar-daddy' relationship, the kept mistress, and the commercial sex industry, with fuzzy boundaries. Just as marriages sometimes involve an *implicit* exchange of beauty (hers) and money (his), affairs are sometimes based on an *explicit* exchange of erotic capital and economic capital.

Swinging, Sex Parties, and 'Open' Relationships

Swinging is a modern egalitarian form of sex orgy. The 'free for all' and competitive nature of the sex orgy means that some participants may have less choice of partner and less luck than others, especially when there are unequal numbers of men and women. Swinging is normally organized around couples (although singles sometimes join in to boost numbers). This ensures balanced sex ratios and equal opportunities for all participants (Brandon, 2008).

Swinging parties are normally arranged in private homes, nowadays through specialist Web sites or magazines. They seem to be more popular with men than women; wives report being pressurized into going along with their partner. They are seen to offer 'fair play', because nonmarital sex is available equally to both spouses, there are no secrets about what happens, everyone is clear that sexual adventure is the main entertainment, there are no emotional attachments, and the

semipublic nature of events eliminates any security risks. However, laws on pimping and brothels can make such sex parties technically illegal – once again underlining the lack of any sharp distinction between amateur and professional sex parties.

Participants in swinging parties sometimes engage in other sexual variations, such as threesomes of one type or another, and voyeurism. This category of nonmarital liaison is strongly focused on sexuality and sexual performance, quite independently of any social or emotional relationships. Swinging thus represents one extreme end of the parallel relationships continuum, along with traditional sex orgies. Catherine Millet's sexual memoirs offer a rare first-person account of involvement in these activities, from the perspective of a woman, one who is also a respected member of the French intelligentsia.

In 2011, Dominique Strauss-Kahn, then head of the International Monetary Fund (IMF) in Washington, became world famous for all the wrong reasons. Arrested in New York for imposing sexual demands on a hotel chambermaid, he was subsequently released without charge (because the woman was an unreliable witness). But he lost his job as head of the IMF, was unable to run for the French presidency in 2012 as he intended, was divorced by his wealthy journalist French wife, and was forced to pay millions in compensation to the hotel maid in order to avoid a civil suit in the USA. In 2013, a former lover published *Belle et Bete*, denouncing Strauss-Kahn's libidinous lifestyle. As details of his lively sexual life flooded into the media, he was shown to lack respect for women, and he became discredited as an academic, intellectual, and politician in France. One of the many media stories concerned his participation in regular sex parties (without his wife) in which prostitutes made up the shortfall of women. Prostitution is legal in France. Even so, Strauss-Kahn insisted he did not know that the women attending his sex parties were professionals – despite the fact that someone paid them. This example illustrates how commercial sexual services and other nonmarital sexual affairs and flings are substitutes for each other, and are enjoyed interchangeably by wealthy libidinous men.

A contrasting case is the Italian business magnate and politician Silvio Berlusconi. While he was President, media stories circulated about the sex parties he attended, to which beautiful call girls were invited. Prostitution is legal in Italy, and Berlusconi, a married man, was never embarrassed to admit that he enjoyed the company of party girls, and paid generously for their time. Despite numerous legal cases against him, including one for his liaison with an underage nightclub entertainer (which is illegal everywhere), he retained substantial public and political support, as evidenced by his party's strong result in the Italian 2013 hung election.

The situation in Puritan Anglo-Saxon countries is quite different. Swinging and sex parties may possibly occur, but the Puritan culture of the USA and Britain ensures they remain hidden and rarely acknowledged.

Sex parties and swinging are probably the dominant form of parallel relationship in the gay community. They generally take the form of gay men visiting gay bars, bathhouses, and parks late at night with a view to achieving one or more sexual encounters. These liaisons can be anonymous, impersonal, and brief. Men with regular partners use such venues as well as the unattached, both heterosexual and openly gay. Heterosexual men also organize and attend sex parties to engage discreetly in homosexual activities while leading a 'normal' heterosexual life. For example in New York, the classic French '5 to 7' *rendez-vous* for affairs is used for private sex parties in hotels, attended by men exclusively. Most then go home to their wives and children and classic heterosexual family lifestyle.

Conclusions

Parallel relationships may be kept hidden, not denied, or admitted frankly in an 'open' primary relationship. They may be publicly accepted or condemned, common or rare, involve amateurs or professionals. But whether they are flings, playfairs, mainly sexual, or romantic–emotional liaisons, parallel relationships remain separate and different from long-term marital relationships. A study of American executives concluded that only 3% of men eventually marry their mistress or lover (Halper, 1988; Hakim, 2012: 22, 277). It appears that partners for long-term and short-term relationships are usually chosen using quite different criteria.

There is no evidence that the expansion in parallel relationships of all kinds in developed economies threatens the institution of marriage. There is good evidence that parallel relationships are a functional alternative to patronage of the sex industry and to serial monogamy in the context of life expectancies of 80–100 years in modern societies of the twenty-first century.

However, for wealthy people who intend to remain childfree, or have already raised children in one marriage and are starting a new solo life as an older nonmarried hedonist, a succession of (multiple) playfairs can become a lifestyle choice. This option seems to be restricted to a tiny fraction of people who are both healthy and wealthy, a group that is coalescing and creating enclaves in locations where the wealthy congregate, such as the south of France and in cosmopolitan cities. For some men, the ideal sexual lifestyle of multiple lovers and playfairs can be realized (Hakim, 2012).

Parenting Attitudes and Beliefs across Cultures

Abstract

This article addresses parental attitudes, beliefs, and more generally parental orientations in terms of some topical categories, that is, parenting orientations and culture, parenting orientations and socioeconomic context, parenting orientations and family change, and parenting orientations and culture contact. Although these areas of study overlap to some extent, they provide a systematic framework to address the important and complex issues involved in parenting. Both contextual and universal approaches are pursued to examine differences and commonalities from a global perspective. A great deal of research is reviewed, and theoretical perspectives are put forward to provide insights into parenting attitudes and beliefs across cultures.

For some time, parenting styles and practices have been the main focus of research on parenting. However, it is now generally recognized that an appropriate model of parenting must also involve underlying factors such as parental cognitions. Although the association between parental beliefs and behaviors is usually found to be modest (belief–behavior dilemma) (e.g., Hofer et al., 2012), researchers have shown that their link is actually stronger when the focus is on implicit behaviors (e.g., nonverbal behavior) or beliefs (implicit cognitions of warmth and power), rather than explicit ones (e.g., verbal behavior or socialization goals) (Keller et al., 2007). This growing confidence regarding the correspondence of parental cognitions and practices has provided an additional impetus for studying parental beliefs. Accordingly, in the last decades, interest in parents' ideas (Cheah and Chirkov, 2008), values (Harwood, 1992) and goals (Durgel et al., 2009; Yagmurlu and Sanson, 2009) has increased. Accordingly, in this article, the authors will use the term 'parenting orientations' with an understanding that it includes parenting attitudes and beliefs, as well as behavior.

Most of the knowledge on parental socialization comes from studies of Western families. However, socialization is culture bound (Kagitcibasi, 2007). Culture influences all processes that affect developmental outcomes; it does not simply affect parental values or behaviors, but it is at the core of them. Children learn values and rules in a cultural context. Cultural values are transmitted to them as they are socialized by parents, family, and other agents in the larger society. Hence, human development must be understood in the context of family and family in the sociocultural context. This is the basic assumption of contextualism, which claims that behavior cannot be understood outside of the context in which it occurs (Kagitcibasi, 2000). The recognition that parental beliefs and attitudes should be studied in sociocultural context is of particular importance to develop an understanding of why certain beliefs show systematic variation among different groups. The answers are often found in underlying functional adaptive mechanisms. Thus, parents' values and beliefs about child rearing reflect parents' conceptualization of the functional attributes of an 'adaptive adult' in that culture (Rosenthal and Roer-Strier, 2001). In-depth studies within context, as, for example, carried out by anthropologists, have stressed the importance of 'lay' theories or beliefs about children, parents, and development, more recently called 'ethnotheories' (Greenfield et al., 2003; Harkness et al., 2011). These belief systems are key aspects of the 'psychology of the caretaker,' which in turn constitutes one of the three components of the 'developmental niche' (Harkness and Super, 1993).

While understanding variations in parental beliefs and attitudes in different contexts is important, going beyond them, one can also search for insights regarding commonalities, even possibly universals, mostly based on shared needs of protecting and nurturing the young and biologically anchored mechanisms of survival. Indeed, a concern for context need not and should not lead to relativism. Rather, one should endeavor to rise to the challenge of integrating the contextual and the universal approaches – "Achieving cultural contextualism without complete relativism" (Kagitcibasi, 2000). Such an approach promises to provide an understanding of the functional mechanisms underlying observed commonalities and differences. Nevertheless, this article is selective in focusing more on diversity, given its cultural emphasis. Notwithstanding this focus, one needs to be careful concerning the meaning attributed to similarities and differences. When a difference is found across cultures, a contextual (environmental) interpretation is used. However, when a similarity emerges, there is an inherent ambiguity here. Because, while shared biology is likely to be the reason, there can be other causes, such as shared psychological, ecological, social, or cultural structures (e.g., all known societies appear to have incest taboo). Or there may be the possibility of an interaction of biology and culture. Research involving evolutionary approaches to the study of culture and biology provides us with new insights into the study of human development in culture, which have implications for variations and commonalities in parental orientations (Keller et al., 2002).

Parenting Orientations and Culture

Given that culture is a powerful context that shapes societal and familial values, one faces the dilemma of coming up with

countless indigenous societal and familial values accompanying countless cultures. Such an approach would yield an unwieldy and basically incomparable body of knowledge. Thus, there is a need for systematic grouping of cultural contexts on the basis of a few underlying constructs that can serve as a paradigm.

Since 1980s, individualism–collectivism is the most widespread framework to explain the role of culture in parenting and indeed in most psychological phenomena (Kagitcibasi, 1997; Triandis, 1995). Although there are numerous definitions of the 'individualism' and 'collectivism' constructs, they refer mainly to cultures' different worldviews, value systems, and approaches to socialization (for an extensive coverage see, Kagitcibasi, 1997). A person in a collectivistic culture defines himself/herself in terms of membership of an in-group (Triandis, 1995). Strong family ties, interdependence, and obedience are valued in such a culture, and an obedience-oriented parenting style is often observed, aimed at achieving a compliant child who gives priority to group needs and close-knit ties. On the other hand, an individualistic culture values personal needs and aims to achieve autonomy and assertiveness in the child (Triandis, 1995). Individualistic parenting style tends to reinforce self-reliance and autonomy in the child, characteristics that are highly valued in individualistic societies. After a decade of extensive research and writing on individualism–collectivism, Markus and Kitayama's (1991) seminal paper has shifted the attention to independence and interdependence. Although different terms are used, there is a correspondence between independence and individualism and interdependence and collectivism. Research has shown that goals related to 'self-enhancement/autonomy' and 'compliance/relatedness to others' highlight a robust difference in maternal socialization across cultural groups.

Much research in Europe and the United States (e.g., Leyendecker et al., 2002; Ragavan et al., 2010) showed that Anglo-American and European mothers placed greater emphasis on individualistic goals (e.g., self-maximization such as self-confidence and self-reliance), whereas Latin-American and immigrant mothers emphasized goals that are representative of a more collectivist pattern (e.g., proper demeanor such as fulfillment of the role obligations and the ability to get along with others). In the same vein, German (Lamm and Keller, 2007) and Dutch mothers (Willemsen and van de Vijver, 1997) are found to strongly endorse independence and assertiveness goals, and even infants are expected to be able to play alone. Similar contrasting results are indicated for Chinese and English mothers. Pearson and Rao (2003) found that English mothers in the United Kingdom underlined the importance of letting the child develop his/her abilities as an individual, and Chinese mothers in Hong Kong were more likely to value filial piety, respectfulness, proper demeanor, and obedience. A study in Australia (Rosenthal et al., 1989) compared Greek-Australians, Anglo-Australians, and Greeks in Greece and their adolescent children. While Greek and Greek-Australian mothers emphasized being good and respectful as desirable child features, Anglo-Australians valued happiness, independence, and assertiveness in the child, which were indicative of individualism.

Further cross-cultural differences are observed in different parenting orientations, including verbal (discourse style) and nonverbal strategies (body contact and face-to-face contact) (Keller et al., 2011). This difference in parenting is stable at least across early childhood (Keller et al., 2010) suggesting that mothers display parenting strategies (e.g., distal vs proximal) that are most conducive to the child's adaptive development in that cultural context (Keller et al., 2011).

Parental beliefs do not concern only children, but also other aspects of family dynamics, including their cognition and construal of their own roles as parents. Parental role definitions have been shown to vary a great deal. For example, while Chinese and Japanese mothers are found to define their maternal roles to include coaching and supporting their children's school-related success (Chao, 2000; Jose et al., 2000), most other mothers do not (Dekovic et al., 2006; Nunes, 1993).

Parenting Orientations and Socioeconomic Context

Parenting attitudes and beliefs are closely related to socioeconomic status (SES) as well as culture. A great deal of research focusing on parental verbal behavior, in particular, has pointed to the variations in early home literacy environment with profound effects on child outcomes along social class differences (e.g., Aksu-Koç, 2005; Hart and Risley, 2003; Hoff, 2003; For an extensive review see Kagitcibasi, 2007: Chapter 3).

From early on, the general conclusion is that there are significant differences among cultural groups but they are lessened when SES (mainly maternal education) is taken into account (Cashmore and Goodnow, 1986). One of the earliest studies that examined the interaction between socioeconomic context and parental orientations is the classical work of Kohn (1963). Taking a sociological perspective, Kohn suggested that social class shapes a person's life perspective. Life perspective has an impact on which personal characteristics are perceived as desirable, influencing parenting goals and disciplinary behaviors. For example, working-class occupations require the person to obey directives of those in authority. Accordingly, working-class parents want their children to be obedient and respectful and they employ power assertion to achieve these functional behaviors. On the other hand, middle-class jobs emphasize self-direction rather than direct supervision; this affects middle-class parents' life perspectives and approaches to child rearing. They employ more autonomy granting goals (e.g., assertiveness and creativity).

Subsequent studies provided support to Kohn's theory (e.g., Ellis et al., 1978). For example, Tugde et al. (1999) showed that American, Korean, Russian, and Estonian parents did not differ in their self-direction goals, but this value was endorsed more highly by middle-class parents. Furthermore, control and discipline were valued more by working-class parents. In accord with this, middle-class children displayed more self-initiation in their activities, which was considered to be related to their mothers' goals for self-direction. Eisenberg (1996) further showed that working-class mothers in both Hispanic-American and Anglo-American families displayed less verbalization and more aversion (e.g., negative affect) in conflict situations than middle-class mothers, but no significant cultural difference was reported. Luster et al. (1989)

investigated American mothers with children 9–23 months old and also found results consistent with Kohn's hypothesis even at this young age. Higher social class standing was positively associated with parents' valuing self-direction (e.g., to think for himself/herself and to be curious about many things) and negatively associated with valuing conformity (e.g., to keep himself/herself and his/her clothes clean and to be polite to adults).

However, other findings contradict Kohn's (1959, 1963) assumption of linearity between parenting and social class (Abell et al., 1996). Harwood et al. (1996) found that although European American mothers coming from a lower socioeconomic background were more concerned with proper demeanor, as opposed to their high SES counterparts who emphasized self-actualization, Puerto Rican mothers coming from both middle and lower socioeconomic backgrounds endorsed goals for proper demeanor highly. Thus, the relative contributions of culture and social class can show variation, and this is an empirical issue.

An early large-scale study on the 'Value of Children' (VOC) (Kagitcibasi, 1982) provided insights into the place of the child in family and society and the changes thereof. The VOC study showed that in contrast with the United States and Germany, obedience was the most valued child characteristic, and independence and self-reliance were the least valued ones in the less-developed Indonesia, the Philippines, Turkey, and Thailand. 'Being close, loyal, and faithful to parents' was an attribute valued in adult children. Old-age security value of children (adult offspring seen as a source of economic security in old age) was also highly valued in less-developed contexts. This value was not endorsed in the United States and Germany, showing that children were raised to become independently functioning adults and were not expected to support their elderly parents. Similarly, another early study investigating parental values in Turkish families showed that parents from lower SES expected their children to be grateful to them when they grow up, whereas high-SES parents valued autonomy and did not expect gratitude, yet they wished for their children to be close to them (Imamoğlu, 1987).

A replication of the 'VOC' study across three generations in Turkey (Kagitcibasi and Ataca, 2005) revealed that material expectations from children declined with socioeconomic development, whereas no such decline was observed for emotional (psychological) interdependence. Other research (Chang, 2006) also suggests that, in line with changing cultural and economic circumstances, Chinese parents are coming to value attributes such as assertiveness, competitiveness and independence more than those traditionally valued such as control and inhibition. Such findings suggest the malleability of parenting in response to changing socioeconomic and cultural demands.

Parenting Orientations and Family Change

Up to this point, this article has revealed a great deal of diversity along cross-cultural, ethnic, and social class differences. At the same time, one sees that family orientations and parenting can change in response to changing sociocultural environmental demands. One is faced with challenges in making sense out of the complexity involved. In particular, one can aim to understand the systematic causal relationships that link culture/society, parenting, and child outcomes. For example, beyond asking 'What are the outcomes of a certain type of socialization?,' one can ask the question 'Why does a certain type of socialization occur in a certain type of context?' Kagitcibasi attempted to address these questions in her 'Family Change Theory' deriving originally from the VOC study results (Kagitcibasi, 1990, 2007; Kagitcibasi and Ataca, 2005). The authors will present this theory briefly as an example of a framework dealing with changes in parenting in response to changes in family and society.

Three prototypical family models are distinguished (Kagitcibasi, 1990, 2007). The first one is the family model of interdependence, which is mostly seen in the collectivistic, traditional, and rural contexts. The family pattern in this model is characterized by overall material and emotional intergenerational interdependence. The child has economic and utilitarian value and contributes to family well-being both as a child and especially as a grown-up offspring, thus the obedience of the child is functional and valued, while autonomy of the child is dysfunctional and is not fostered. This is because an autonomous child may grow up to be an independent young adult who attends to his/her own needs more than those of the family. Thus, the parenting style in this model is obedience oriented, and the self-developing in this family is the 'connected/relational self.' The contrasting model, the family model of independence, is prototypical of the individualistic Western middle-class nuclear family where intergenerational independence is valued. In this family model, relatively permissive and self-reliance-oriented parenting is functional since autonomy and separation/individuation are considered to be prerequisites of healthy development. The 'separate self' develops in this family. The third family model is prototypical of the urbanizing, more developed sectors of collectivistic societies with higher education. It entails material independence and psychological interdependence between generations. With increased affluence and changing life styles, dependence on the offspring for old age security decreases. Therefore, obedience-orientation decreases, and autonomy is granted in child rearing. Also, autonomy of the growing child becomes adaptive in higher education and specialized employment contexts that require individual decision making. However, given the collectivistic culture, the family still values close familial ties. Hence, the self-developing here is the 'autonomous-related self.'

Kagitcibasi's (1990, 2007) family change theory explains the relative salience of autonomy and/or relatedness in child-rearing orientations as a function of the family patterns that are impacted by both socioeconomic and also cultural factors and changes in these. It points to the possibility of being both autonomous and related. Furthermore, as autonomy and relatedness are generally considered to be basic human needs, the autonomous-related self is proposed as a healthy model of self (Kagitcibasi, 2007, 2012). The above discussion pointed to the importance of living conditions and environmental demands and the changes in these for parenting beliefs and behaviors. It is important to analyze these links among contextual factors and parenting to

understand why parents behave as they do. As mentioned earlier, parents have ethnotheories; they are aware of the adaptive value of different child characteristics and adjust their child-rearing orientations accordingly. The different family models discussed above render different child outcomes more or less functional.

Several studies provide supportive evidence for the family change theory (see Kagitcibasi, 2007 for an extensive review). For example, using in-depth semistructured interviews, Yagmurlu and colleagues (Yagmurlu, 2009; Yagmurlu et al., 2009) found that socialization goals of the less-educated Turkish mothers typically exemplify the family model of interdependence. These mothers mostly mentioned being kind and considerate toward others, and being compliant to societal norms as desirable child characteristics; and they emphasized an anticipation to be looked after by their children when they get older. However, mothers with high education tended to set socialization goals that enhance self-reliance and autonomy more than dependency. Nevertheless, maintaining warm and close relationships with family was a goal that these mothers shared with the less-educated mothers, in line with an earlier study by Imamoğlu (1987), mentioned above. Thus, socialization goals of the mothers with high education exemplify the family model of psychological interdependence. This implies that psychological interdependence is needed and preserved in the face of rapid urbanization, modernization, and economic development (Kagitcibasi, 2007).

Comparative work across countries concur. Mayer et al. (2012) in a study using the recent VOC study results from Germany, Turkey, and India found three different clusters corresponding to the independence, psychological interdependence, and the interdependence family models. As expected, the highest prevalence of the independent family model was found in Germany, that of psychological interdependent model in Turkey, and that of interdependent model in India. The relative significance of the utilitarian VOC (material interdependence) in the family emerges as the key factor differentiating the three family models. This factor is directly influenced by socioeconomic characteristics such as affluence. In the same vein, in a 27-country study with university students, Georgas et al. (2006) found evidence for the prevalence of the psychologically interdependent family.

Parenting Orientations and Culture Contact (Immigration and Acculturation)

The discussion up to now, especially in the last section, has drawn attention to the interactions between context (cultural and socioeconomic environment) and family/parenting orientations. The home culture (e.g., the values, practices, and cultural background of the child's immediate family) and the societal culture, together form the 'dual climate' of culture (Greenfield and Suzuki, 1998). In general, the 'cultural climate' in these two contexts is not very different; cultural/societal values and parental values tend to be congruent. However, at times there can be mismatches between changing environmental requirements and parenting conventions, which can cause problems for all concerned. When changes are profound, such as in immigration or sudden social change, the likelihood of mismatches may increase.

Thus, studying parenting in acculturation contexts gives us further insights into the dynamics of stability and change in parenting orientations. Indeed, the distinction between the home culture and the societal culture is usually larger for immigrant or minority children in multicultural societies. Immigrant children learn the norms and practices of the dominant culture through their peers and teachers at school and through other channels such as the media. Immigrants' parenting values and practices may also change as they are exposed to the host society (Bornstein and Cote, 2006).

When people move to a new culture, they take their cultural values and beliefs with them, and the reciprocal relations with the dominant society influence these original cultural values and beliefs. Berry (1997) defined this process of acculturation in terms of the immigrant's attitudes toward maintaining his/her own cultural identity and/or becoming a part of the host society, and described four types of possible response to the host culture – assimilation, separation, integration, and marginalization. These 'acculturation strategies' have significant implications for parenting orientations in culture contact contexts.

Reviews of research on ethnic and minority parenting (e.g., Garcia Coll et al., 1995) reveal that acculturation is an important predictor of mothers' developmental expectations, values, parenting style, and interaction with the child. Most studies that pertain to acculturation and parenting have been conducted in North America, Australia, and Europe. Research with Mexican-American groups showed that first-generation Mexican immigrants promoted greater interdependence than later generations (Delgato-Gaitan, 1994), and those mothers who were more integrated to the US culture (as indicated by their language preference) displayed less hostile control and inconsistency in their disciplinary strategies (Hill et al., 2003). Similarly, Puerto Rican mothers who embraced US values were found to display more warmth and involvement in their parenting (Calzada and Eyberg, 2002), and living in the United States was associated with a reduction in their use of corporal punishment (Jambunathan and Counselman, 2002). Aycan and Kanungo (1998) showed that Indo-Canadian immigrants who endorsed an assimilation attitude were more likely to support autonomy in their children, particularly in social life. Those who were integrated emphasized the role of parents in both guiding children toward schooling and career choices and teaching responsibilities toward the family. Indo-Canadian parents who tended to separate from the dominant culture favored control over children and attached more significance to moral life.

A study conducted in Australia with Greek immigrant mothers' parenting values and goals showed a shift toward the values of Australian mothers (Rosenthal et al., 1989). They combined an emphasis on autonomy goals, as the Australian mainstream mothers did, and on being respectful, like the Greek mainstream mothers. Yagmurlu and Sanson (2009) also found that Turkish immigrant mothers who had a tendency to integrate with Australian society reported higher levels of self-direction goals and inductive reasoning,

and lower levels of compliance goals and obedience-demanding behavior. Similar results were found in research conducted on parenting goals of immigrants in Europe. Leyendecker and colleagues have shown that second-generation Turkish mothers in Germany valued autonomy and self-maximization of their children significantly more than first-generation mothers (Leyendecker et al., 2006). However, even second-generation Turkish immigrant mothers expected their children to be respectful, starting from the early ages, like first-generation mothers. In a study with Dutch, German, Turkish-Dutch, and Turkish-German mothers, Durgel et al. (2009) found that Dutch and German mothers displayed a family model of independence, whereas Turkish immigrant mothers favored an interdependence model. Those who were more adjusted to the mainstream culture endorsed autonomy goals more, such as professional and educational success, and demanded less obedience from their children, thus moving to a 'psychological interdependence family model.' This study showed that family change theory (Kagitcibasi, 1990, 2007) was useful in understanding changing parenting orientations in immigration contexts.

In general, these studies point to the greater adoption of host society parenting orientations through generations. However, there are complex issues involved in acculturation research. For example, the SES standing, especially the education of the parent needs to be considered. Often, low-educated working class immigrants reflect interdependent traditional family values, while more-educated immigrants from the same original country may have psychologically interdependent families. Their parental orientations and relative adoption of host culture norms tend to be different. Another issue concerns the Western individualistic theoretical assumptions of the researchers. Because often there is not much recognition of the psychological interdependence family model and the autonomous-related self (Kagitcibasi, 2007), close-knit family relations and parental control tend to be interpreted in negative terms. For example, when Dekovic et al. (2006) in their study of several ethnic minorities in the Netherlands found that parents use strict discipline, but they are also warm toward their children, they called this an 'unlikely combination.' Indeed, Gonzales et al. (1996) noted earlier that often ethnic minority parents are too readily labeled authoritarian because they appear too controlling to the Western mainstream culture researcher. Some recent volumes on acculturating families and parenting orientations in culture contact aim to provide new insights into these complexities and address problems and their solutions (e.g., Bornstein and Cote, 2006; Masten et al., 2012).

In conclusion, one can say that examining family in culture contact contexts leads to a better understanding of how parenting orientations change. This article has attempted to address parental attitudes, beliefs, and more generally parental orientations in terms of some topical categories, that is, parenting orientations and culture, parenting orientations and socioeconomic context, parenting orientations and family change, and parenting orientations and culture contact. Although these topical areas of study tend to overlap to some extent, they provide a systematic framework to address the important and complex issues involved in parenting orientations across cultures.

This article is a revision of the previous edition article by M.A. Payne, volume 16, pp. 11045–11048, © 2001, Elsevier Ltd.

Abstract

This article examines the concept of parental engagement with children's learning. First it looks at what this concept entails, then at the value that this concept has been shown to have. It then moves on to examine how support can be offered for parental engagement, under the headings of home–school links, and support and training for parents; both of these sections include examples. The article then moves on to examine the barriers to parental engagement, then to critique the field of research around this topic, and to suggest future areas for research.

Parental Engagement with Their Children's Learning

What Is Parental Engagement in Children's Learning?

Parental involvement with the learning of their children may be rightly called ubiquitous – from a child's first moments of life, it is interaction with their parents and carers. (In this article, the term 'parents' is used to signify those adults who have the primary care of minors.)

Children learn the basics of social interaction from their parents and within the family unit. This learning link to parents – and the wider group of the family and community – continues throughout the child's life. Although schools and school staff have long acknowledged the importance of this learning link (with early parent-education classes being offered in the mid-1800s in the USA; Turney and Kao, 2009), it is only with the rise of compulsory schooling, and the view that education takes place within the boundaries of the school, that there has been a need to investigate the role that parents play in relation to their children's learning. What has come to be acknowledged with increasing force over the past 30 years is the value of parental engagement with children's learning. Conceptions of this process have also changed, and we are now able to state that, when properly supported, parental engagement with children's learning can be "one of the most powerful levers for school improvement" available (Harris and Goodall, 2008). This article approaches the issue in relation to parental engagement in children's learning aligned to the work of schools, as both have the same ultimate aim, that of the best possible outcome for the child.

Originally, all learning took place within the family unit. Early interventions were aimed at supporting parents in relation to child health, and in creating healthy, well-disciplined homes. However, as early as in 1977, there was a call for training to support parents to negotiate educational and social systems (Gordon, 1977). By the late 1980s, there was research highlighting the value of supporting parents of preschool children (Powell, 1989). Governmental agencies took up the banner, mandating parental involvement and participation in schools and other agencies. In fact, there was support even in the mid-1980s for parents teaching their children to read and write (Berger, 1991). In spite of these calls and evidence, however, parental engagement with their children's learning still lacks adequate support in many schools.

Recently, there has been a move from conceptions of parental involvement (see, e.g., Baumrind, 1989; Catsambis, 2001; Brooks, 2004; Berthelsen and Walker, 2008), to a discussion of parental engagement (Barton et al., 2004; Carréon et al., 2005; Harris and Goodall, 2008; Epstein, 2009; Hollingworth et al., 2009; Goodall and Vorhaus, 2011; Goodall, 2012, 2013; Goodall and Montgomery, 2013). Encompassed within this change is a more fundamental movement, from seeing parents as secondary partners in the schooling of their children, to seeing them as fundamental to the wider concept of children's learning. We may now define parental engagement as "parents' engagement in their children's lives to influence the children's overall actions" (Kim, 2009: p.89).

This article addresses parental engagement in the following sections, namely the value of parental engagement, support for parental engagement and the forms it can take, barriers to that engagement, critique of the research in the field, and areas for further research.

What Is the Value of Parental Engagement?

Literature in the field, while not unanimous and while certainly not complete (Goodall and Vorhaus, 2011), gives strong indications of the value of parental engagement with children's learning. The value of this engagement is not necessarily affected by the background of the family (Catsambis, 2001; Sylva et al., 2003). Parental engagement can be shown to be positively associated with children's achievement (Smith and Hausafus, 1998; Harris and Goodall, 2007; Hill and Tyson, 2009; Jeynes, 2012) and with children's self-regulation in learning (Xu et al., 2010); supporting parental engagement can impact positively on young people's motivation, self-efficacy, engagement in learning, and achievement (Fan and Williams, 2010).

There is a need for a broad understanding of learning and education. While it is clear that children learn in venues other than school, 'education' is often considered to take place within schools alone. However, children's achievement can be supported by blurring these lines; training parents to teach their children to read (rather than merely listening to them doing so) can have significant positive impact (up to 6 months of reading

age; Erion, 2006; Sénéchal and Young, 2008; Sylva et al., 2008b).

Parenting programs, aimed at supporting parenting skills, appear to have more modest but still positive effects, leading to reductions in tension between parents and teenage children (Ralph and Sanders, 2003), better relationships between parents and school staff, and increased bonding between mothers and young children (Erion, 2006; Reid et al., 2007; Lexmond et al., 2010), and increased parental confidence (Norwood et al., 1997). The positive effects of even short-term interventions to support parenting have been recognizable over many years (Brooks et al., 2008).

Afterschool, family engagement programs have been shown to have a positive effect on students (Lexmond et al., 2010) and attainment (McDonald et al., 2006; Brooks et al., 2008), in both literacy and numeracy.

Support for Parental Engagement

Parental engagement may usefully be discussed under two headings: home–school links and support and training for parents. It should be stressed, however, that these are not separate strands, which can stand alone. The greatest benefit from support for parental engagement will come from holistic, coordinated efforts.

Home–School Links

This need for 'joined-up thinking' is nowhere more clear than in the area of home–school links. To adequately support parent's engagement, there is a need for a whole-school approach, underpinned by a broad understanding of that engagement, and supported by senior leaders.

Good results have been found when schools are proactive in working with parents, and where the process is supported by senior leaders (Redding et al., 2004; Etsyn, 2009). The links between home and school need to be based on an understanding of cooperation and partnership (Goodall and Montgomery, 2013). Examples of successful programs which have forced such links and had a positive impact on children's achievement include the Manchester Transition Project (Dyson et al., 2007), Solid Foundation Schools (Redding et al., 2004), School Home Practitioners (Rogers et al., 2010), Homes School Knowledge Exchange (Greenhough et al., 2007), and the Parent Support Advisor Trial (Lindsay et al., 2009).

Part of an effective exchange of knowledge between home and school relies on the information passed between them. Studies have found that not all information sent to homes by schools is fit for this purpose (Crozier and Davies, 2007; Harris and Goodall, 2007). Information needs to be in language(s) and formats which are accessible to parents, and which contain information parents can use to support the learning of their children. Parents given clear, easily followed suggestions are more able to support their children's learning than those given more general information (Toomey, 1993).

This exchange of knowledge works best when it is based on a broad and accurate understanding of parental engagement. Research has shown that parents, school staff, and children conceive of parental engagement differently (Martinez and Velazquez, 2000; Harris and Goodall, 2007). The engagement which is most valuable is support for learning in the home (Desforges and Abouchaar, 2003; Sylva et al., 2008a), which aligns with what older pupils reported seeing as the greatest value of parental engagement – moral support (Harris and Goodall, 2007). Schools may not recognize all the forms of support parents are giving to students (Lopez et al., 2001), leading to an undervaluing of parents by schools, and contributing to feelings of alienation by parents.

Examples

In this area, as in all others, it is very important that interventions are underpinned by a coherent, whole school approach. Examples under this heading would include out-of-hours activities (clubs, the FAST program, and outreach programs). Links can also be forged by careful planning of school work to include parents, and by activities designed to help pupils link home and school (homework about interviewing family members and bringing photos of home to school).

Support and Training for Parents

Interventions to support parental engagement are more effective if they are based on clear knowledge and understanding of the needs and desires of parents (Lopez et al., 2001; Carpentier and Lall, 2005; Feiler et al., 2006; Brooks et al., 2008; Statham et al., 2010). Parents may need support in areas such as literacy and numeracy to support their children (Statham et al., 2010). Programs to support parents also need to show cultural sensitivity to parents and communities (Kumpfer and Alvarado, 2003).

Research has shown that parental engagement is enhanced when parents receive clear, targeted information about supporting their children, rather than more general information. Parents also benefit from a clear understanding of what any school-based interventions will entail.

Examples

Parent-to-parent tutoring has been shown to be effective, allowing parents to feel more relaxed and confident. Training parents to teach their children to read, as mentioned above, has also been shown to have significant benefits, as can more general programs aimed at supporting parents' learning, such as Supporting Parents on Kids' Education (SPOKES).

What Are the Barriers to Parental Engagement in Children's Learning?

In various studies, parents have reported a number of barriers to their engagement with their children's learning, and to engaging with schools about that learning. The two most often reported barriers are time (Peters et al., 2007) and their own experience of education (Harris and Goodall, 2008; Harris et al., 2009).

Parents have reported a number of ways that lack of time poses issues for engagement. In relation to engaging with schools, parents are often unable to come into school during the day due to other commitments (work, caring for other children or relatives). These same commitments may also make it difficult for parents to find time to interact with their children at home.

Secondly, parents have reported that their own, negative experiences of education can present a significant barrier to anything which requires their presence at school or interaction with school staff. To overcome this, schools must seek to build up trust with groups of parents, to allow them to form new concepts of schools and schooling.

There are other issues which may also prevent parents from engaging with their children's learning or with schools. Numerous authors have discussed a cultural and social gap between groups of parents and schools (see the subsequent section), which renders some groups of parents less able to negotiate the school system or make their needs known. Many parents also experience difficulties with English, particularly if schools do not make information available in a range of languages.

Critique of Research in the Field

The foregoing must not be seen as offering parental engagement with children's learning as a panacea or uncontested good. Particularly, in the last few years, legitimate critiques of the concepts have risen. These tend to center on two questions. The first question, raised above, centers around the exact definition of parental engagement. Above, we examined the issue of differing definitions of parental engagement between different stakeholder groups; here, the issue relates to differences in perception of parental engagement between cultural groups. This is most obvious when there is a cultural gap between parents/families and school staff.

Research has critiqued the concept of parental engagement as given in the literature as one that reflects the practice of white, middle-class families. The practices of other groups are, therefore, sometimes perceived as lacking or in deficit and parents have reported feeling disenfranchised, with their support of their children being undervalued or ignored. Further, parents and families are conceived to be homogeneous groups, when in fact they exist in great variety. Many parental engagement interventions are seen to support what the school sees as good for students (and parents), and the appropriate roles for both, rather than being based on a cooperative stance between parents and teachers. Some parental engagement programs can actually be detrimental, in that they have been found to reinforce existing power differentials between parents and schools (Crozier et al., 2000; Henderson and Mapp, 2002).

Lack of educational experience and engagement can reduce the value that parents are able to take from interventions to support them (Manz et al., 2010), just as the lack of this experience can be a barrier to engagement. It is also possible that programs do not seem to have cultural validity for some groups of parents, where the values and norms of parents are not taken into account (Manz et al., 2010). However, when programs are appropriate and sensitive to the needs and norms of parents, significant benefit can be derived for children from disadvantaged backgrounds, outlasting the effects for more advantageous peers (Brooks et al., 2008).

The second question is raised around the claims made for parental engagement (Hartas, 2008). It is notoriously difficult to make robust claims of causality in educational research, and the area of parental engagement is no exception. It is very difficult to isolate the effects of any given intervention among the myriad of influences on the achievement of young people.

Future Research

As noted, while the field has benefitted from a considerable array of research, there are still significant gaps in the literature base. Further work is needed, particularly around issues such as access and equity, as well as wide-scale testing and trial of interventions to determine good and best practices across a wide range of families.

Conclusion

As can be seen, parental engagement with children's learning is an important area of school and educational life. It is not, however, an area which has received enough research and there are a number of significant questions still outstanding. We do not yet have enough information about the effects of various interventions, nor do we know enough about how to support different groups of parents. We do know that engaging parents in their children's learning is a significant lever for improvement.

Abstract

Fritz Wilfried Pareto was born on 15 July 1848 in Paris, France, the son of an Italian political émigré. Due to an amnesty granted by the House of Savoy, the Pareto family was able to move back to Italy. Fritz Wilfried's given name was italianized and shortened to Vilfredo. He enrolled at Torino's *Scuola di Applicazione per Ingeneri*, where, in 1870, he received his doctorate. In 1882, Pareto, retired from his career as a manager with the *Societá dell'Industria di Ferro*, resolved to dedicate his remaining life to his scientific pursuits. Italy's leading economist at the time, Maffeo Pantaleoni, lent his support when Pareto was named to the Lausanne University chair held previously by Léon Walras. As an academic teacher, Pareto had considerable success. His busy teaching schedule did not keep him, however, from publishing his *Cours d'économie politique*, a masterpiece of neoclassical economic theory. In *Les systèmes socialistes*, Pareto concluded that, theoretically, a socialist economy might be able to solve its problems as well as any nonsocialist economy. In his *Manuale dieconomia politica*, Pareto presented a reworked version of his theory of economics with special emphasis on the various states of economic equilibrium. In the two volumes of his *Trattato di sociologia generale*, Pareto undertook the immense task of integrating his economic and social analyses: 'Economics is but a small part of sociology, and pure economics is but a small part of economics'. Proud of his anticipatory powers, he foresaw the catastrophic repercussions of the Treaty of Versailles – for purely economic reasons. As early as 1917, he had asked, 'whether the Pax americana will turn out to be as productive as the onetime Pax romana?' Pareto died on 23 August 1923. He was buried in Céligny, his last place of residence, in a modest grave listing only the years of his birth and death, and his *nom de guerre*.

Life

Fritz Wilfried Pareto was born on 15 July 1848 in Paris, France, the son of an Italian political èmigrè, Raffaele Pareto (1812–82). Raffaele's father, Raffaele Benedetto Pareto (1768–1831), had been made a marchese di Parigi – or, as some have claimed, even a pair de France – by Napoleon, in recognition of his collaboration in erecting the Cisalpine Republic. The Pareto family was rooted in the trade bourgeoisie of Genoa, Italy, where it had been registered in the *Libro d'oro*.

In addition to her son, whose given name was Italianized and shortened to Vilfredo, Pareto's mother, Marie Mètenier (1816–89), also had two daughters. Due to a political amnesty granted by the House of Savoy, probably as early as 1858, the Pareto family was eventually able to move back to Italy. Pareto's father started to work as a French instructor for Genoa's *Scuola di Marina*. Vilfredo attended the same school, the beginning of his Italian education. When, later, Pareto's father was offered a better position in Turin, Vilfredo followed him to the capital of the Kingdom of Savoy. Here, in 1867, Vilfredo received his *Licenza in scienze matematiche e fisiche*.

He then enrolled at the *Scuola di Applicazione per Ingeneri*, where, in 1870, he received his doctorate. Much later, Pareto still considered his dissertation – on 'Principi fondamentali della teoria di elasticità dei corpi solidi' – important enough to include it in his *Collected Essays on Economic Theory*. He began his professional career in Florence, working for the *Centrale della S. A. delle Strade Ferrate Romane*. From there, he went on to a management position with the *Societá dell'Industria di Ferro*, traveling widely in Germany, Austria, France, England, and Switzerland.

His career left him with a sound knowledge of practical business matters. In 1882, the year his father died, Pareto chose professional retirement and settled in Florence. At around this time, he made an unsuccessful attempt at running for political office on a platform promoting his ideal of a liberal market economy. Pareto became resolved to dedicate his remaining life to his scientific pursuits. He joined Italy's oldest learned society, the highly respected *R. Accademia Economico-Agraria*. He also became a member of a second society, *Adamo Smith*, where he gave several lectures on scholarly topics and economic policy, which he also published. Moving in the upper-class circles of Florence – which then exerted a leading cultural influence throughout Italy – Pareto made a number of influential friends: the Lord Mayor Peruzzi and his wife; the politician S. Sonnino; P. Villari, who wrote a famous biography of Machiavelli; Colli, the author of *Pinocchio;* the anthropologist Mantegazza; such renowned philologists as D. Comparetti, A. Franchetti, and A. Linaker, as well as several others. It was at this time that he married Alessandra (Dina) Bakounine (1860–1940), a Russian (no relation to the anarchist of the same name).

When Pareto met Italy's leading economist, Maffeo Pantaleoni, they soon became friends. Pantaleoni supported Pareto, as a successor had to be appointed for the Lausanne University chair held by Lèon Walras, who had had to vacate his position due to his worsening mental illness. As an academic teacher, Pareto had considerable success. However, he soon asked to be relieved of his teaching duties. An unexpected inheritance set him free to concentrate on his preference for research and scholarship. Pareto's *Feste Giubilari* was published in 1917 to great critical acclaim. While this represented a personal triumph for him, Pareto continued to view himself as a victim of Italy's politicians and the *Camorra universitaria italiana*. When the Fascists took over Italy's government, various honors were offered to

him; he either declined them explicitly or did not respond to them at all.

Only once did Pareto return to Italy and then only because he was forced to visit the Rome family record registration office in person. To get a divorce and be able to remarry, he needed his birth certificate. Dina, his first wife, had left him. In the summer of 1923, he married Jeanne (Jane) Régis (1879–1948), his second wife. He had met her through a newspaper advertisement in Paris. When Pareto died two months later, on 23 August 1923, he no longer possessed an Italian passport. To be able to marry Jane, he had been forced to turn in his passport at the Republic of Fiume. Conforming to his last wishes, he was buried in Céligny, his last place of residence, in a modest grave listing only the years of his birth and death and his *nom de guerre*.

Works

From his beginnings as a researcher, Pareto placed immense importance on the question of method. He had named his approach the logical-empirical method. In his *Manuale d'economia politica* (1994), first published in 1906, he devoted no less than 55 paragraphs to it. In his *Trattato di sociologia generale* (1983), that number rose to 144 paragraphs. 'My only intention,' Pareto wrote, 'is to describe facts and to draw logical conclusions from them' (Pareto, 1983: p. 55). Facts were to be weighted according to relevance, not quantity. Facts based on experience were considered valid only 'as far as experience does not contradict observation' (Pareto, 1983: p. 6).

Pareto considered this method applicable not only to the field of economics but to the social sciences as well and – implicitly or explicitly – to every field of scholarship (Pareto, 1994: Vol. 1, 14). However, every inductive approach will always contain an implicit assumption. In the sciences, this would be the supposedly homogeneous character underlying all of nature. Thus, Pareto's 'survey' is strongly similar to J.A. Schumpeter's concept of 'vision.' According to Pareto, it is quite feasible to differentiate between economic and social phenomena initially. To regard them separately does not violate the dictates of empiricism. But 'both parts then have to be integrated with each other. Only a full view of the whole thing possesses any empirical reality' (Pareto, 1994).

At the heart of Pareto's *Cours d' économie politique* (1896–97, 2 Vols.) lies his theory of economic equilibrium. He refers to two sets of mathematical equations to describe two 'economic systems.' One system applies to barter and exchange, the other to production. If combined, both sets of equations attain validity only in a state of equilibrium (Pareto, 1994, App. 131–133). 'The most interesting case,' according to Pareto, is described as a situation where the number of equations is less than the unknowns contained in the equations: 'The system is then flexible and can balance itself' (Pareto, 1994, App. 131–133). 'Mathematics,' Pareto insisted, 'should be used only if it allows for an expression of certain relations between facts which otherwise could not have been expressed or which could not have been formulated using standard language' (Pareto, 559, n. 4, cf Pareto, 1983, 1732).

To describe different states of economic equilibrium, Pareto coined two terms: ophelemité and utilité. When Irving Fisher wrote a review of Pareto's work, Pareto tried in vain to discourage Fisher from confusing his terms with the terminology of Walras and Edgeworth. Fisher, Pareto argued, did not understand enough French and even misunderstood some of Pareto's mathematics (Pareto, 1960: Vol. 3, p. 408).

In 1902–03, Pareto published the two volumes of *Les systèmes socialistes*, an incisive analysis of historical and present-day socialist theories, including a discussion of Werner Sombart (he had treated Karl Blücher in a similar way in his earlier *Cours*). He paid due reverence to Karl Marx as a sociologist. Economically, however, he did not give Marx much credit. Theoretically, a socialist economy might be able to solve its problems as well as any nonsocialist economy. Earlier, Pareto had already integrated socialist society and collective capital with his overall theory of economics (Pareto, Vol. 2, pp. 714–724). Indeed, his followers, E. Barone and O. Lange, later based their own socialist theories of economics on this insight. Pareto argued against socialism not on economical, but on social and anthropological grounds. He concluded that all socialist systems were eventually based on untenable social and anthropological contradictions.

In his *Manuale d'economia politica* (1994), Pareto presented a reworked version of his theory of economics with special emphasis on the various states of economic equilibrium. Typically, he differentiated between them in his famous dictum:

> We can say that the members of a community, in a certain situation, enjoy the optimum of ophelemit if it has become impossible to distance oneself from this situation even to a small degree without benefit or damage to all members of this community; even the smallest step then necessary leads to profit for some members of the community or loss for others. (Pareto, 1994: p. 33)

This concept has been named the Pareto optimum. Later, it served as the foundation for welfare economics. It led to several attempts at an improved theory of income distribution.

Pareto always insisted that to understand his *Manuale*, one needed to know his *Cours*. In a typical misreading, J.R. Hicks complained that in the *Manuale* – by now a classic on the theory of consumption – the problems of capital and interest were hardly noted (Hicks, 1950), ignoring their extensive treatment in the *Cours*.

It was Pareto's intention to show 'by examples rather than declarations to prove the relation between economic phenomena and other phenomena of society' (Pareto, 1994, Foreword). Thus, it becomes clear how deplorable was the omission, in the French edition of the *Manuale* (Pareto, 1981) of Pareto's Foreword or *Proemio*. Still, improvements had been made to other parts of the French edition, including Pareto's mathematics. He was of the opinion that 'pure' theory was applicable only to the flow of goods and trade within a 'purely' competitive economy. Yet, the reality of monopolies, cartels, and trusts asked for a different description of modern markets and their mechanisms. Eventually, he discarded his entire theory of economic equilibrium as a 'dead end,' in spite of his groundbreaking anticipation of what later essentially came to be called the

theory of monopolistic competition (cf the French edition of the *Manuale*, Vol. 3, 40–48, 160–164, Vol. 5, 8–9, 71; App. 141). With reference to the effects of economical cycles, Pareto already differentiated between their objective and subjective sides. In this, he could claim no less a predecessor than Montesquieu.

Pareto's final great work, the *Trattato*, was preceded by the brief *Mythe vertuiste et la littérature immorale* (Pareto, 1911), an unforgiving settling of scores with any kind of literary censorship. Taken to its logical conclusion, Pareto argued, censorship would have to call for all of world-class literature to be censored – starting with the Bible.

In the two volumes of his *Trattato di sociologia generale* (1983), Pareto undertook the immense task of integrating his economic and social analyses. It had long been clear to Pareto that for any model of economic action fully to grasp reality, it had to encompass a theory of society. Next to those actions described as logical, recognizably illogical actions had to be equally accounted for. Such actions called illogical by Pareto are regularly cloaked by pseudo-logical explanations. On this insight, Pareto erected an entire sociology of knowledge (cf Eisermann, 1987, pp. 170ff.). Logical actions, to Pareto, were not synonymous with rational actions, however. For any act to be described as rational, it would have been necessary actually to look into the mind of the social actor. Pareto did not think such introspection was feasible. Rather, he conceptualized such actions as residual social facts. Thus, Pareto arrived at an inventory of six residues, in which instinct of combinations and persistence of aggregates were the most important ones.

He distinguished between two groups of economic actors: 'rentiers' and 'speculators.' Rentiers in general are secretive, cautious, timid souls, mistrustful of all adventure, not only of dangerous ventures but also of any venture to have even the remotest semblance of not being altogether safe (Pareto, 1983: p. 2313). Pareto's rentiers are ruled by aggregates of persistence and his speculators by their instinct of combination. Speculators

> are usually expansive personalities, ready to take up with anything new, eager for economic activity. They rejoice in dangerous economic ventures and are in the watch for them, but they work underground and know how to win and hold the substance of power, leaving the outward forms to others. (Pareto, 1983: p. 2313)

Accordingly, Pareto expanded his analysis of the economic equilibrium into an analysis of the social equilibrium (Pareto, 1983: pp. 2067–2087). The crucial movement inside the system of society is construed as *circolazione delle classe scelte*, class circulation. Society is then ruled by fractions, or minorities, which are subject to a continuous turnover, or exchange (2025–2046 and throughout).

Pareto always insisted that his 'pure' theory simply was an integral part of his overall economics, and that his economics necessarily formed part of his sociology. He claimed to have introduced the principle of relativity to the social sciences. He took equal pride in his anticipatory powers of foresight. Like his contemporary J.M. Keynes, he foresaw the catastrophic repercussions of the Treaty of Versailles – for purely economic reasons. As early as 1917, he asked, 'whether the Pax americana will turn out to be as productive as the onetime Pax romana?' (Pareto, 1960: Vol. 3, p. 240).

Abstract

The parietal lobe is one of the four major divisions of the cerebral cortex. The function of the parietal lobe is to transform sensory input into motor output. This transformation is influenced by a host of cognitive computations processed by the parietal lobe including attention, spatial representation, number processing, and memory. Ultimately, the parietal lobe integrates sensory, motor, and cognitive information for the production of purposeful guided behavior.

Introduction

The parietal lobe constitutes approximately one-fifth of the cerebral cortex. Situated in a pivotal location, the parietal lobe receives projections from the frontal, occipital, and temporal lobes. Broadly speaking the parietal lobe has two main functions: somatosensation and sensorimotor integration. The parietal lobe can be considered the 'association cortex' as it integrates visual, auditory, and somatosensory information for the purpose of guiding behavior. An example that illustrates the integrative functions of the parietal lobe is a behavior that we perform multiple times on a daily basis: reaching and grasping for objects. Imagine, for example, reaching for and picking up a glass from the dinner table. This seemingly simple action requires the visual system to extract information about the location and the intrinsic properties (e.g., size, shape) of the glass, and then process this information in order to plan and execute the movement. Once grasped, sensory receptors in the hand assess properties of the glass such as weight, texture, and temperature. This information will in turn be used to modify the details of the grasp in order to successfully transport the glass to the mouth. In addition, the parietal lobe plays a key role in processing information about the spatial arrangement of the body with respect to the glass, and the location of the glass with respect to the other objects on the table. The parietal lobe is also essential in a number of cognitive functions such as attention, numerical processing, and working memory. Together with the frontal lobe, the parietal lobe demonstrates the greatest evolutionary expansion in terms of cortical size. Relative to body size, the human parietal cortex is 20 times larger than it is in other primates. This expansion has been attributed to the increased complexity of visuospatial integration, multimodal processing, and cognitive abilities supported by the human parietal lobe.

The bulk of our knowledge regarding the functions of the parietal lobe has come from the study of patients with lesions to this area of the brain. The neuropsychological lessons have highlighted how important the integrity of the parietal lobe is to the processing of sensory information, sensorimotor transformation, and spatial computations. More recently and with the advent of modern functional neuroimaging, mainly functional magnetic resonance imaging (fMRI), much more has been learned about functions of the parietal lobe particularly with respect to cognitive abilities such as attention, memory, and number processing.

The following sections will describe the anatomy and main functions of the parietal lobe. Particular emphasis is placed on the major deficits associated with damage to this part of the brain.

Gross Anatomy and Functional Divisions

The parietal lobe is located under the parietal bone, which forms the lateral wall of the skull just above the ear. The parietal lobe is superior and anterior to the occipital cortex, posterior to the frontal cortex, and superior with respect to the temporal lobe. The parietal lobe is bound by four prominent sulci (see Figure 1): anteriorly, the parietal lobe is separated from the frontal lobe by the central sulcus (cs); posteriorly, separated from the occipital lobe by the parieto-occipital sulcus; laterally, separated from the temporal lobe by the lateral sulcus (ls; with the supramarginal gyrus (SMG) extending upward into the parietal lobe from the dorsal edge of that sulcus); and medially, the longitudinal fissure divides the left and right parietal cortices. The parietal lobe can be subdivided into two functionally distinct zones: the primary and secondary somatosensory cortices (S1 and S2 respectively) in the anterior zone, which are the main areas responsible for processing the sense of touch, and the posterior parietal cortex (PPC) which is, broadly speaking, the area responsible for sensorimotor integration and control.

Primary and Secondary Somatosensory Cortex (S1, S2)

Anatomy

S1 and S2 are located on the anterior edge of the parietal lobe, bordering the primary motor cortex (M1; Brodmann's area (BA) 4) on the dorsal boundary of the frontal cortex. This region (anatomically referred to as the postcentral gyrus, PoG) is delimited anteriorly by the cs and posteriorly by the postcentral sulcus. It extends laterally from the longitudinal fissure to the ls (Sylvian fissure). S1 is located superficially, and is composed of BAs 3, 1, and 2. S2 is located on the superior bank on the ls. In addition to all three subdivisions of S1 being interconnected, S1 has connections to the frontal lobe, specifically both the M1 (BA 4) from BAs 3 and 2, and the

Figure 1 Schematic representation of human parietal lobe. Numbers represent main divisions.

premotor cortex (BA 6) from BA 2. S1 has projections to the PPC (BA 5) and S2 from all three BA subdivisions. Area S2 is densely interconnected with the contralateral S2, and also projects to area parietal ventral (adjacent anteriorly to S2), the PPC (BA 7b), the insular cortex, the amygdala, and the hippocampus.

Functions

S1 and S2 receive information from receptors in the skin (touch, pressure, vibration, temperature, and pain), and proprioceptive information from receptors in the muscles and joints. This information is utilized for detecting the presence and magnitude of sensory stimuli as well as its location on the body surface. S1 contains a tactile *homunculus* (Latin for 'little person') – a representation of the entire human body. This representation in the somatosensory cortex is not a true copy of the body; instead it is distorted. The largest proportion of S1 is dedicated to receiving input from areas on the body with highest receptor density and thus greatest sensitivity (i.e., the hands and face). Patients with damage to S1 or S2 have difficulty with tactile perception on the side of the body opposite to the lesion (i.e., the contralateral side). This deficit is more noticeable in the hands and face and could present as a loss of touch, temperature, pain, and/or proprioception. In addition, anosognosia, hemianesthesia, and astereognosis are three well-characterized disorders that arise from damage to S1 and/or S2.

Deficits Associated with S1/S2 Damage (Most Common)

Anosognosia

Perhaps the most extreme deficit that results from lesions to S1 and S2 is anosognosia (denial of motor deficits). This neurological condition is characterized by the patient's inability, or refusal, to acknowledge motor deficits on the contralesional side of the body. In extreme cases patients will deny the presence of a limb altogether, or report it as belonging to someone else. Anosognosic behavior may be exceptionally illogical in this regard, as the patient may admit the affected limb is attached to his/her shoulder, while simultaneously insisting it belongs to someone else. Anosognosia most frequently occurs following unilateral or bilateral lesions of S1 and S2, though it may be associated with frontal and/or temporal lesions, especially if the lesion-affected area encompasses both parietal and frontal structures. Though many regions have been reported to have a critical role in the cause of the disorder, damage to the thalamoparietal radiations within the right optic thalamus and/or damage to the right parietal cortex appears necessary to produce symptoms of anosognosia. Though anosognosia is most often diagnosed following right parietal lesions, this may be confounded by the fact that patients with left parietal lesions are often aphasic, and thus unable to communicate the symptoms of the disorder.

Hemianesthesia

Hemianesthesia describes a condition wherein patients lose complete pain, temperature, and/or tactile sensibility on one side of the body, while retaining motor ability. Hemianesthesia most often affects the left side, following damage to the right parietal cortex (primarily S1), though left parietal lesions may also result in right-side symptoms. As diagnosis usually follows a patient's failure to report tactile sensation on one side of the body, hemianesthesia diagnoses may be confounded in cases of unilateral neglect or hemi-inattention.

Patients with hemianesthesia may retain (or, more commonly, regain) motor ability in the affected limb despite persistent loss of somesthetic sensitivity. Interestingly, patients

may be able to localize tactile stimuli, despite being unable to accurately report whether or not a stimulus even occurred. For example, a patient may be unable to differentiate between hot or cold, rough or smooth, or heavy or light, but may be able to correctly report whether an 'unfelt' stimulus occurred on his/her fingers or palm, or his/her hand or forearm. This 'blind touch' phenomenon suggests an unconscious network processing somesthetic input – one that is spared following lesions to S1.

Astereognosis

Astereognosis is a disorder described by a loss of ability to discriminate between familiar objects based on touch alone. Despite tactile sensation being otherwise intact, patients with this disorder show a distinct loss of size and shape discrimination ability on the contralesional side. Astereognosis results after damage to the somatosensory hand area, located on the anterior middle third of the PoG (S1).

Posterior Parietal Cortex

Anatomy

The PPC is split longitudinally by the intraparietal sulcus (IPS), which divides the PPC into the superior parietal lobule (SPL; BAs 5, 7a and 7b) and the inferior parietal lobule (IPL; BAs 40 and 39). *Superior Parietal Lobule*: In the SPL, BA 5 is a sensorimotor region that receives input from M1, S1, and BA 7b ipsilaterally, and BAs 2, 5, and 7b contralaterally. It projects to the premotor, motor, and sensorimotor cortices, as well as the arcuate and principal sulci, cingulate, basal ganglia, superior temporal gyrus (STG), and claustrum. BA 7a is an area important for spatial perception; it is a visuomotor area, whereas BA 7b is somatosensory. Area 7a is connected to areas in the occipital (V6) and temporal cortices (in the parahippocampal cortex), as well as inferotemporal cortex (IT, area preoccipital inferotemporal cortex). Area 7a is also connected to other regions in the parietal lobe (both SPL, IPL, and all along the IPS), the frontal cortex (via the frontal and supplementary eye fields, and BAs 46 and 45), and the cingulate. Area 7b is also connected to visual areas (V6) and IT; BA 5, the medial dorsal parietal area (MDP), and BA 7a in the SPL; medial superior temporal area (MST) and superior temporal polysensory area (STP) in the temporal lobe; areas 45, 46, and 12 in the frontal cortex; and the cingulate and insular cortices. *Inferior parietal lobule*: IPL is anatomically and functionally divided into two gyri: the SMG and the angular gyrus (AG; anterior and posterior IPL, respectively). The AG (BA 39) is posterior to the SMG and superior to the temporal lobe. The SMG (BA 40) lies at the posterior end of the lateral fissure, continuous with the postcentral and superior temporal gyri. SMG has connections to the frontal and prefrontal cortices, the caudate nucleus, the parahippocampal gyrus, the hippocampus, the precuneus, the superior frontal gyrus, and the SMG.

Anteroposteriorly, the IPS divides the PPC into the anterior intraparietal (AIP), the medial intraparietal (MIP), the lateral intraparietal (LIP), and the ventral intraparietal (VIP) areas. AIP receives input from the caudal IPS, and projects to area F5 in the ventral premotor cortex, caudal (PMc). MIP, in the posterior half of the medial wall of the IPS, connects to other areas in the parietal lobe (including area 5, V6, V6a, and VIP) and projects to the premotor cortex. The LIP runs along the lateral wall of the IPS and is important for planning saccades. As such LIP is connected to many areas in the visual (occipital) cortex, somatosensory and sensorimotor (parietal) cortices, and the frontal eye fields and area 46 in the frontal cortex. It also has subcortical connections to the superior colliculus (SC) and pulvinar nucleus. Finally, VIP is roughly the middle third of the bottom trough ('fundus') of the IPS. It receives input from somatosensory (BAs 2, 5, and 7), visual (LIP, V6, and MST), and polysensory cortices (MIP, MDP, and area temporal – parietal – occipital area). VIP projects to area F4 in the PMc.

Functions

Generally speaking, the PPC is responsible for visually guided movements, as well as keeping track of 'mental space' for the processing of numerous spatial tasks. PPC neurons are very active when an action is performed toward an object, or even if attention is shifted toward that object. The neurons in the PPC are feature-sensitive; some react to size, others to shape, or orientation. These neurons are therefore thought to be responsible for determining appropriate hand posture for grasping. The PPC also directs saccadic eye movements, such that the fovea centers on an object of interest. PPC neurons are particularly sensitive to 'rewarding' stimuli; that is, stimuli that have behavioral relevance. PPC also contains neurons that are part of the mirror neuron system (*see* Premotor Cortex). Patients with PPC lesions are impaired at mental manipulation and mental rotation tasks, particularly after lesions to the PPC in the right hemisphere. PPC lesions can also result in impairments in the ability to perform mental arithmetic, syntax in language, movement sequence coordination, and/or recognition of familiar objects when viewed from novel angles. PPC lesions could also lead to Balint's syndrome. This syndrome consists of deficits in orienting the eyes to a certain location, spatial neglect, and optic ataxia (explained below).

Perhaps one of the most well-studied functions of the PPC is that of visually guided actions such as reaching and grasping. The dorsal visual stream (as described by Goodale and Milner) runs along the PPC. In their account of how the primate visual system is organized, Goodale and Milner proposed that the dorsal 'action' stream, which projects from early visual areas to the PPC, provides the flexible control required to act upon objects in the world. Neuropsychological and imaging research has supported this proposal. Using fMRI, research has shown that the IPS is activated during reaching movements, with stronger activation of the lateral and medial IPS during pointing movements, and the anterior IPS becoming activated when viewing or manipulating graspable objects, especially tools. Furthermore, recent fMRI studies have shown that regions within the PPC are selectively activated when planning reach-to-grasp movements. Specifically, these studies have revealed that the superior parieto-occipital cortex is involved in determining whether an object is within reach, whereas the anterior intraparietal sulcus becomes active when one is planning to grasp an object. Progress has been slower in mapping the visuomotor functions of the PPC and the parietal lobe in

general, compared to other areas because of the technical challenges of designing neuroimaging studies involving action. The next 10 years, however, should be filled with exciting discoveries as more ingenious protocols and sophisticated analysis tools become available.

Other functions of the PPC include attention (*see* Attention, Neural Basis of), language (*see* Speech Processing, The Cortical Organization of), spatial cognition (*see* Spatial Cognition), and number processing (*see* Numbers and Number Sense). Regarding PPC's role in attention, fMRI studies tell us that the IPS is activated when visual attention is directed toward a specific location, and the right temporoparietal junction becomes activated when visual targets are detected in unattended locations. The PPC is also known to be involved in processing the meaning and phonology of written words. Damage to the IPS, particularly the SMG, leads to phonological errors in naming (e.g., spaghetti named as 'pasghetti'). Additionally, PPC handles quasi-spatial processing, such as the spatial processing involved in mathematics and reading. Damage to this area can result in acalculia (inability to perform simple mental arithmetic), impaired cross-modal matching (being unable to recognize an object across two or more sensory modalities), right–left confusion, drawing disorders, and other spatial ability impairments. Damage to the PPC (especially the IPS) can also result in object manipulation deficits and apraxia. fMRI studies reveal that the human IPL (specifically the posterior part of the right-side SMG) contains a network of mirror neurons, homologous to that found in the macaque ventral premotor cortex and IPL. Finally, PPC (the right IPL) is also critical for self-recognition; if this area is stimulated by repetitive transcranial magnetic stimulation, a person's ability to recognize their own face from an array of other familiar faces is selectively disrupted.

Deficits Associated with Posterior Parietal Damage (Most Common)

Apraxia (Lesions Including but Not Limited to IPS)

Apraxia (*see* Apraxia) is a disorder of voluntary movement that cannot be explained by weakness, spasticity, rigidity, akinesia, sensory loss, or cognitive impairment including language comprehension. Patients with apraxia are unable to carry out learned, skilled motor acts despite preserved motor and sensory systems, coordination, comprehension, and cooperation. Although apraxic patients understand the meaning of gestures and objects, they often display difficulties imitating these same gestures, performing meaningful gestures on command, and using tools and objects. Apraxia is seen more frequently after left hemisphere damage, but unlike other parietal lobe disorders (e.g., hemispatial neglect), unilateral lesions often affect both sides of the body. This suggests that the left PPC plays a special role in the planning and control of skilled voluntary movements.

Oculomotor Apraxia (Lesions Including but Not Limited to LIP)

The PPC, specifically the LIP, is crucial in the planning, generation, and control of saccadic eye movements (*see* Eye Movement, Control of (Oculomotor Control)). Bilateral damage to LIP leads to oculomotor apraxia: an inability to shift gaze to objects in the visual periphery. Patients with oculomotor apraxia present with random eye movements. Patients may present with the inability to maintain fixation on a stimulus or, conversely, they may display difficulties in moving gaze away from a specific focus of fixation.

Optic Ataxia (Lesions Including but Not Limited to SPL, IPS)

Patients with optic ataxia show great difficulty reaching and grasping for objects particularly when reaching in the periphery. This impairment is accompanied by inappropriate hand orientation and grip formation. Optic ataxia appears more severe after left hemisphere damage when compared to right hemisphere damage. Patients with left hemisphere damage show a 'hand effect' and have great difficulty reaching toward objects and shaping their grasp appropriately with their right hand anywhere in space. With their left hand, however, the deficit is apparent only in the right visual field (the field contralateral to the lesion). Patients with right hemisphere damage do not show a hand effect and their deficit in visuomotor control is limited to the field contralateral to their lesion. That is, they can acquire objects successfully when reaching with either hand into the right visual field, but show deficits with both hands when reaching for objects in the left visual field. This finding suggests, again, that the left PPC plays a special role in visually guided actions.

Hemispatial Neglect (Lesions Including but Not Limited to IPS, AG, STG)

Hemispatial neglect (*see* Hemispatial Neglect, Neural Basis of) is characterized by the inability to orient toward and attend to stimuli in contralesional space. Neglect is most frequently seen after unilateral brain injury, especially the right hemisphere. Patients with neglect often present with loss of awareness in the left side of space (or right side for patients with left hemisphere lesions), responding slowly or completely ignoring visual, auditory, and/or somatosensory information from that hemifield. In extreme examples of neglect a person may not be aware of the deficit, so they might not eat food on the left side of their plate or they may ignore the left side of their body. For example, they may not shave or apply makeup to the left side of their face. Because patients with neglect often present without any visual field deficits, hemispatial neglect has long been considered an attentional problem, rather than a sensory one. In fact, there is evidence that posterior parietal neurons participate in the control of attention. Imagine the earlier scenario of reaching and grasping for a glass at the dinner table; visual awareness will be necessary to selectively direct one's attention to the target (i.e., glass) and not to the other many objects on the table.

Acalculia (Lesions Including but Not Limited to the Left IPS, AG)

Patients with acalculia (acquired calculation deficit) demonstrate difficulties comprehending and producing Arabic numerals (*see* Numbers and Number Sense). It is characterized by more severe deficits when reading three-digit numbers as

opposed to one- or two-digit numbers. Because acalculia can present with the inability to recognize one's own fingers (finger agnosia), it has been speculated that acalculia may originate from impairments in relating numbers and fingers by using finger-counting strategies.

Working Memory Deficits (Lesions Including but Not Limited to SPL)

Evidence is accumulating that the PPC plays an important role in working memory (*see* Working Memory, Neural Basis of), particularly in object working memory. Patients with lesions to the right PPC display impairments in remembering sequentially presented objects or object locations even when a few objects are used. Deficits in working memory have also been documented for both auditory – verbal and visual – spatial stimuli, especially in the mental manipulation of such information in working memory.

Conclusion

In summary, the primary role of the parietal lobe is to transform sensory input into motor output. This transformation does not occur in a vacuum but rather within a rich context of cognitive computations including attention, spatial representation, number processing, and memory. Ultimately, the parietal lobe integrates this sensory, motor, and cognitive information for the production of purposefully guided behavior.

Parliamentary Government

Abstract

Parliamentary democracy is the product of the twentieth century in most countries. Before 1918 there were waves of democratization, which mostly did not exceed parliamentarization of constitutional regimes. Criteria for the notion of parliamentary democracy are developed and various types (including semi-presidential systems) are differentiated. Functions of parliaments in parliamentary systems and the policy performance of this type of government compared to others are evaluated.

Development of Parliamentary Regimes and Democracy

Parliamentary democracy is the product of the twentieth century and in many countries developed only after 1918. There were some attempts to create such a system during the European revolutions of 1848 without leading to consolidated systems. What Huntington has called the first long wave of democratization (1828–1926) in the light of research on parliamentary systems was only parliamentarization. Parliamentary government is characterized by a government *responsible to the majority in parliament*. Democracy was added to the parliamentary regimes only later. The minimal criterion of democracy is *universal suffrage*. In most countries with a regime of constitutional monarchy, such as Britain, Scandinavia, or the Benelux countries, democracy was introduced later than parliamentary regime. Only in some rather authoritarian monarchies was democratic universal suffrage introduced or preserved without granting a parliamentary regime with responsible government (France, 1851 in the Second Empire Germany 1871 in the Empire of Bismarck) (see Table 1).

Only in a few countries (France, Finland, Sweden) was the process of parliamentarization and democratization synchronized. A continuously democratic parliamentary regime existed only in France. Even Britain – the mother of 'parliamentary government' – in the nineteenth century could not be called a 'parliamentary democracy' (cf. Table 1). There was a divergence of *parliamentarization* (mostly implemented by liberal majorities which were reluctant to add universal suffrage to the system) and *democratization* (frequently introduced under the pressure of radicals and socialists). These groups were initially unwilling to accept the checks and balance of the liberal parliamentary regime and advocated a democratic regime with many features of plebiscitarian instead of representative democracy. Only when they came to power did they slowly accept the rules of the game which were mostly developed in former constitutional monarchies.

Democratization in some countries has ruined the parliamentary system (Italy, Austria, Germany, Spain) when counter-regime forces gained power. In other established parliamentary systems the regime in the 1930s came to the brink of a collapse (Belgium, France) under the pressure of right-wing extremism. Only after 1945 and the disastrous experiences with authoritarian or even totalitarian dictatorship, were parliamentary government and democracy combined in peaceful coexistence. Some countries (such as the Federal Republic of Germany) even then, however, showed a tendency to emphasize the legal state and *representative* parliamentary *government* much stronger than *democratic participation*. The theory of constitutional and representative government did not easily accept parliamentary democracy but interpreted the preponderance of the parliamentary majority in terms of a rather mechanistic system of checks and balances and 'mixed government.' Because responsible cabinet government developed first in Britain and Belgium, the jurists for quite a time used the term '*Coburg government style*.' Only since the 1830s was the term 'parliamentary government' accepted in Britain and France and the regime was recognized not only as a mode of governance but as a *regime sui generis* which made the old typologies of regime types according to the number of rulers rather obsolete.

Types and Criteria of Parliamentary Democracy

There are many types of parliamentary government, but most of them have developed common *institutional* criteria.

a. *Compatibility of parliamentary mandate and ministerial office* (exceptions are the French Fifth Republic, Luxembourg and The Netherlands) in order to guarantee close cooperation between the parliamentary majority and the executive.
b. Prime ministers are normally *members of parliament*.
c. The government has to have the confidence of the parliamentary majority. *Ministerial responsibility* is not defined in terms of legal responsibility as in dualistic constitutional monarchies. The government has to resign in the event of a vote of no-confidence unless it chooses to ask the head of the state to dissolve parliament in order to give the electorate the opportunity to resolve the conflict.
d. Parliament controls the *government by raising* questions, exercises the right to interpellate and set up committees of enquiry, which facilitates the decision about whether the strongest sanction or a vote of no-confidence should be used. This right is shared by dualistic presidential systems, apart from the possibility of toppling the head of government and his or her cabinet.

Table 1 Parliamentary democracy: the merger of parliamentarization and democratization

	Continuity of a system of estates transformed into a constitutional regime						*New regimes*		*Parliamentarization of neo-absolutist regimes*				
	UK	*Sweden*	*Norway*	*Finland*	*The Netherlands*	*Luxembourg*	*Belgium*	*France*	*Italy-Piedmont*	*Spain*	*Germany*	*Austria*	*Denmark*
General male suffrage	1918	1921	1898	1906	1917	1919	1919	1848 1875	1919	1869 1907	1871 1919	1907	1915
Time of creation of a government responsible to parliament	1688ff 1832–35 Final conflict	1917	1884	1906	1868	1868ff	1833ff	1821ff 1837 1848–51 1871ff	1860	1874ff	1918	1918	1901

e. Some analysts have postulated as an essential feature a formal vote of the government at its first meeting with parliament (investiture), as in the French system under the Third and Fourth Republic and in Italy, or even demanded the formal election of the prime minister, which was developed in the German Basic Law of 1949. Most parliamentary regimes do not accept this condition.
f. More widespread is acceptance that *parliament* should be *dissolved* if the prime minister has lost the confidence of the parliamentary majority. Sometimes this has not been instituted, for example in Norway and Israel. In other cases the legal possibility of dissolution has become inapplicable because it has been abused by unparliamentary presidents, as in the Third French Republic (when President MacMahon dissolved the Chamber of Deputies in 1877).

Besides the minimal institutional criteria, certain social structural features are essential for the consolidation of parliamentary government:

1. *Organized parties* to facilitate the building of parliamentary majorities.
2. Party-building to facilitate the development of *cabinet solidarity*.
3. Development of the *office of prime minister*. In early systems where the estates dominated, and even in certain absolutist monarchies, the power centers – the estates or the crown – impeded the activities of first minister. A certain *hierarchization of the ministerial council* also strengthens cabinet solidarity.
4. Development of a *political culture* favorable to appropriate parliamentary behavior and alternating government.

Not all these institutional criteria can be found in every type of parliamentary system. Therefore subtypes have been proposed. Most ideological is the distinction between *authentic British parliamentarism* and the allegedly *inauthentic parliamentary system of the French type* – close to revolutionary government. Latecomers to parliamentarization, such as Germany (1918) and Sweden (1917), have often denounced the dangers of the French type, especially the German school of Redslob.

Oddly enough, France itself has reacted strongly against the shortcomings of the parliamentary system of the Third and Fourth Republics. De Gaulle's constitutional ideas, close to those of Carré de Malberg and later developed by Michel Debré were first pronounced in 1946 in the famous speech of Bayeux but failed to obtain majority when the Fourth French Republic was developed in 1946/47. But De Gaulle got his revenge when the Fourth Republic collapsed and he was able to shape the institutions of the Fifth Republic according to his ideas. A new system was born that since Duverger has been called the *semipresidential system*.

In spite of its name this was clearly a subtype of parliamentary government though the double responsibility before parliament and the head of the state – which existed in constitutional monarchies such as that of Louis Philippe – re-emerged. But in the long run the dominance of parliament in executive-legislative relations is re-established. De Gaulle's new system was not new at all: it had developed as a Republican type of constitutional regime from 1848 (the Second French Republic, 1848–51) and re-emerged in the Weimar Republic (1919) and Finland. Semipresidential systems are not a mixed type, not even the 'three-quarter presidential system' that Yeltsintried to develop. The backlash of a humiliated legislature was felt in Russia in 1998 when Yeltsin was forced to renounce Chernomyrdin as prime minister and accept the parliamentary candidate Primakov.

Functions and Performance in Parliamentary Democracy

Parliaments were more powerful in times of parliamentary sovereignty without universal manhood suffrage than in modern parliamentary democracies. The main actor in parliamentary democracy is no longer parliament or government, but the two powers are linked together. This linkage has strengthened the prime minister in most parliamentary regimes, unless high party fragmentation and consociational practices of conflict resolution have weakened the head of the government. Parliamentary democracy seems to be misnamed because of much discussion on the 'decline of parliament.' Therefore, *cabinet government, prime ministerial government, or chancellor's democracy* became more popular to characterize the bigger parliamentary regimes.

Parliamentary systems have to perform various functions. There is no general decline of parliament but rather a change of the main functions of the system. *Parliamentary control* is weakened in systems with close relations of parliament and government, interlaced by party government. The *controlling functions* declined or shifted to other institutions from constitutional courts and courts of account to the mass media. *Representation* and *articulation of interests* in the systems has changed over time. The *legislative function* is still important because more social problems are regulated in modern democracies than in old constitutional regimes. The *recruiting function* of the system, however, is strengthened after democratization of the parliamentary regimes.

Parliamentarians have become less removed from their voters in terms of *social structure*. What has been called *virtual representation* in early parliaments for those not eligible to vote in *postparliamentarism* is true of the social ties between deputies and voters. But people have adapted to this development and demand less strongly to be represented by members of the same region, the same sex, the same profession, or the same social class. The influence of voters on the selection of representatives is still mediated by the parties and their formal members. Primary elections can undermine the selecting function of the parties among other disadvantages, such as a lower voter turnout in the general election. Modern democracies are not ruled according to President Lincoln's Gettysburg formula of government *of* the people, *by* the people, and *for* the people. The distance of the representatives is compensated for by increasing *responsiveness* and sensibility to the wishes of the voters. Government *for* the people in the modern democracy of fluctuation of mass public moods has increased rather than decreased.

Nonetheless the departliamentarization of democracy is lamented. This has a *domestic political* side. At the stage of policy formulation, the practice of expert committees working together with the government is growing stronger. In the decision-making arena, the government is the most important initiator of legislation. Informal initiatives behind the formal initiatives of advisory boards, constitutional courts, or international

organizations are further undermining the part played by parliamentarians in legislation. The penetration of interest groups into the work of ministers and parliament has shifted the preparatary work to a round tables of extraparliamentary committees and working teams. But parliament is not just a rubber stamp to ratify the decisions of networks outside parliament. Parliaments, formally the institutional seat of the people's sovereignty, represent the framework for the coordination of networks of actors from parliamentarians, party strategists, interest groups, ministry officials and in federate states the federate units. The cosy triangles of early American parliamentary studies, composed of parliamentarians, bureaucrats, and interest groups, have become uncosy squares, since party steering was rediscovered in the 'legislative Leviathan.' In federal states such as Germany, deparliamentarization at the Länder level has led to greater participation of the Länder in the national decision-making process via intergovernmental decision-making. This further actor has been added, making an uncosy pentagon. The Maastricht Treaty has increased the number of areas that are subject to EU rules and legislation. With growing competence at the EU level, lobbying at that level is likewise growing. Meanwhile, national parliaments – more than the executive – have been downgraded to the position of lobbyists. Paradoxically the *democratization* of the European Union has led to *deparliamentarization* at the national level. Until 1979, Members of the European Parliament were tied to the national parliaments, but since the introduction of direct elections this has no longer been the case. However, the European Parliament does not yet pose a real threat to the national parliaments as it can only draw up laws when asked to do so by the Commission. Formally, EU legal acts are passed by the Council of Ministers and not by the European Parliament.

There are three threats to parliamentary democracy:

1. In the Process of *regionalization*, regional assemblies will try to strengthen themselves via regional politics at the cost of national parliaments.
2. In the process of *Europeanization*, more and more domains of the national parliaments will be regulated by the EU. This process will be supported by the activities of the European Court and the gradual standardization of the national legal systems.
3. In the process of *globalization*, a consolation at the national level is the fact that worldwide organizations such as the World Trade Organisation and GATT are starting to retaliate to the EU for what it did to the national decision-makers because the room for maneuver of the European organizations is increasingly limited by the global level, although still strongly limited in some arenas.

Abstract

A Parliament is a central institution of the democratic state under the rule of law. A Parliament is a representative institution, usually elected by direct universal suffrage. Political scientists and historians study parliaments from closely related viewpoints. The functions of parliaments differed according to the system of government. Contemporary parliaments are classified as bicameral or unicameral, as 'active' or 'deliberative.' Modern parliaments stem from two roots: first, the corporative assemblies of the Estates that were summoned under the Ancien Regime in Europe, and the second, the broad-based popular representation originating from revolutionary movements. The role of parliaments evolved during the course of the nineteenth century from being initially consultative to being deliberative. Central to an understanding of the evolution of parliaments is the concept of popular sovereignty. There are five principal trends in the historical research on modern parliaments: recovery and systemization of sources; sociological analysis of the composition of parliamentary representation; a prosopographic examination of parliamentary speeches; analysis of the role and impact of parliamentary speeches; and analysis of the role of parliaments in public administration.

Nowadays, a Parliament is a central institution of the democratic state under the rule of law. The term Parliament comes from French and describes a forum in which social understandings are reached by verbal negotiation, through the act of speaking. A Parliament is a representative institution, usually elected by direct universal suffrage. It plays an indispensable role in the workings of the State, as an active participant in the coalescing of political will, in public management, and essentially through conduct of the legislative process and concentration of the ruling elite. The decisive function of policy legitimization performed by parliaments is central to representative democracy, which is the predominant system of political organization in contemporary states. Experience of direct democracy, which dispenses with the representative parliamentary system or acts in parallel to it, is generally limited to referenda, Switzerland being among the few countries that practice direct democracy on a regular basis. A Parliament is an assembly of public delegates who receive a mandate for a limited period, are voted to office through elections based upon a pluralistic political party system, and serve as a channel for the expression of the opinions of society.

The approaches of political scientists and historians to the study of parliaments are closely related. Most contemporary researchers apply the insights of both disciplines in their efforts to analyze and explain the institutional structures and workings of parliaments. Comparative studies of the trajectory of societies, formation of states, and composition of their social and economic groups are the components of research on representation, participation, and decision-making processes conducted through and by means of parliaments. The achievement that parliamentary institutions represent, in terms of the development of democracy within society throughout the nineteenth and twentieth centuries, provides the social sciences with ample scope for research. Political science, sociology, and history continually delve into the origins, composition, work methods, social relevance, political prominence, and social roles of parliaments.

Functions and Types

The functions of parliaments have differed according to the system of government. Various terms may designate a parliamentary institution according to the different systems, such as: parliament, court, assembly, council. Under a parliamentary system, executive power emanates from the legislative branch invested in parliament, and governments hold office and remain in power so long as they enjoy the confidence of the parliament. Under a presidential system, parliament serves as a counterpoint to the political legitimacy bestowed upon the president through direct presidential elections. Parliaments also exist in nondemocratic regimes, such as the fascist dictatorships and 'democratic peoples' republics' of the twentieth century. Under such systems they tend to be mere puppets or facades since they exercise no real power but rather serve as stamps to endorse the power of the government, devoid of the legitimacy bestowed by a pluralistic party system and in the absence of representative electoral processes.

Depending on the process leading to their formation, parliaments can be classified according to three criteria: composition, action, and structure. Composition is subject to two variants: the first of these relates to criteria based on noble birth or propertied status, whereas the second is based on universal suffrage. Functionally speaking, contemporary parliaments can also be classified as bicameral or unicameral, depending on the constitutional framework of the State, which may have opted for a single chamber or two chambers. In any case, the chamber (or at least one of the chambers) ought to be elected directly by the people in free elections.

In functional terms, parliaments may be classified as 'active' or 'deliberative.' Active parliaments are those that, within a parliamentary system, have the power to appoint and support the government, as is the case in most modern parliamentary democracies. The so-called deliberative parliaments are those that have no direct responsibility for the business of the government, and include the pro forma parliaments tolerated by authoritarian regimes. Under a presidential system, as

a counterpoint to the legitimacy of the 'working' Executive Branch, the parliament assumes a predominantly deliberative role. These characteristics apply equally to unicameral and bicameral parliaments, in both federative and centralized states.

It is the decisive role performed by parliaments in the process of forming governments and providing them with support that has given currency to the term 'Parliamentary System' to describe the form of government in which empowerment and support of the Executive Branch are dependent on a vote of confidence from the parliament. This definition applies to the form of government, a term that expresses the legitimacy that stems from the legislative branch in its executive form. Under a presidential system in which the Executive Branch is the predominant branch of the government, as is the case in the United States or in Brazil, the Head of State is voted to office by direct elections and consequently his legitimacy competes with that of the parliament. In both parliamentary and presidential systems, the parliament is said to embody the Legislative Branch and its political legitimacy stems from the ballot.

Origins

Modern parliaments stem from two roots. The first of these is the corporative assemblies of the Estates that were summoned under the *Ancien Regime* in Europe, and the second, the broad-based popular representation originating from revolutionary movements. The first model of corporative representation brought together the three Estates – namely, the nobility, the clergy, and the 'Third Estate' that evolved gradually into a form of parliamentary representation as sovereign rulers required assent to levy taxes and make war. This first version of the dependence of the sovereign ruler on an institution of a parliamentary nature did not lead directly to democracy or recognition of popular sovereignty. The origin of these lies in the second root of modern parliaments – the popular revolutionary root – from which stem: the origins of the process of definition of popular sovereignty, the concept of citizenship, the legitimacy of power based on representation and the delegation of sovereign power, the rule of impersonality of the law within the context of absolute civil equality among citizens, the extension of such rights to all adult citizens within society and adoption and consolidation of liberal democracy, the expansion of suffrage and political parties, the constitution of government and of its control (under both the parliamentary and presidential systems), and the expression of popular will through the ballot. Both roots reflect antiabsolutist sentiments and it is from them that a representative democratic model, with elections at predetermined intervals, developed.

Both these origins of parliamentary power are clearly preserved and apparent in the structure and functioning of the British Parliament. The House of Commons, based upon the weight it amassed in the Civil War of 1642–49 and the upon manifestation of its social power in the Glorious Revolution of 1688–89, assumed its role of expressing the will as a source of power detrimental to that of the Crown. The result of the revolution, which established the right of the parliament to close a new sovereign, is reflected in the jusnaturalist and contractual arguments presented in Locke's *Two Treaties on Civil Government* (1690) – one of the principal theoretical works in support of the legitimacy and controlling powers of parliament.

The House of Lords, with its elitist composition, preserves the corporativist tradition of the Estates. Modern French tradition, established with the Jeu de Paume Oath of 20 June 1789 at the advent of the French Revolution, signals a break with the system of Estates General of the *Ancien Regime* and use of the Parliament to designate the judicial and notarial functions, as it had since the twelfth century. The parliamentary assembly installed in the very earliest days of the revolution enshrined the principal of popular sovereignty. In both the British and the French cases, affirmation of the principle of popular sovereignty arose from revolutionary movements, whereby the political absolutism of European states was substituted by constitutionalism. The role performed by a representative system in the formation of the United States is unique. The affirmation of the will of the Americans against unconditional rule by the British Crown led to the establishment of a community-based version of the decision-making process, similar to the community practices of the Protestant congregations, which served as a collegiate political model for the provincial and continental congresses, in which no form of corporative representation was present.

Evolution

At the onset of the nineteenth century, there were three types of parliaments: mixed-popular and aristocratic-bicameral under the English model; the French unicameral, popular model; and the American bicameral, popular and federalist model. In Western Europe and Latin American republics, an era of constitutionalization began. Both monarchies and republics adopted political systems dependent on representative legitimacy. Under parliamentary systems (in which the Government is dependent on investiture by the Legislative Branch), and under presidential systems (in which the Executive is chosen by direct elections), parliaments assumed increasing importance in political life. Parliament became the forum for representation and expression of social and economic forces, where the repercussions of rights claimed took on resonance and the extension of political and civil rights was played out.

The role of parliaments evolved during the course of the nineteenth century from being initially consultative to being deliberative. The legitimacy of parliaments became independent of the legitimacy of the sovereign upon emerging from the electoral process. As a consequence of electoral and census systems, which, throughout the 1800s, maintained cultural and economic distinctions among citizens, despite their all being held (theoretically) equal before the law, parliaments maintained an indirect corporative dimension until the institution of universal suffrage. Such distinctions were based on the systematic exclusion of women and the preference for the rich, the wellborn, and the literate.

The itinerary of consolidation of the power of the Legislative Branch was implemented in different ways under the North American presidential, the British parliamentary, and the French and German parliamentary models. The United States

Congress reflects the federative structure of state and the fact that the United States spent the nineteenth century engaged in a process of expanding its frontiers and acquiring new territory. Furthermore, the political model adopted by the American Congress implies that each state of the federation, through actions taken by its own political spheres, has joined the Union. The principle of legally joining a federation of states, together with that of popular sovereignty, is enshrined in the bicameral parliamentary systems predominant in federative states (such as the United States, Canada, Australia, Brazil, India, Austria, Mexico, Argentina, Germany, Japan, and Indonesia). In centralized states, bicameralism is the result of the continuity of mixed forms of representation, with roots stemming back to the Estates and to popular sovereignty. Both the British and the French parliamentary systems provide examples of such evolution. In both cases, tradition has been partially preserved through the upper house (the House of Lords and the Senate), whereas, popular representation is ensured by the Lower House (the House of Commons and the National Assembly). This model was also adopted by the Scandinavian monarchies and also, at specific times, by such states as the German Empire (1871–1918) and the multinational Austrian-Hungarian Empire (1848–1918).

Parliaments emerged upon the European scene as a counterpoint to monarchic autocracy. In their contemporary form as 'parliaments of citizens,' they emerged from an extensive line of development going back to the principle of egalitarian representation first put forward in the eighteenth century. The parliamentary model of the late twentieth century is the fruit of the maturing of philosophical concepts with respect to the human rights and the separation of powers. As the twenty-first century evolves, there is widespread social awareness that there can be no exercise of power without political representation, and that this resides in the legislative bodies. The transformation of political regimes into full-fledged democracies has led to an expansion and diversification of the roles of parliaments. To the role of authorizing tax collection has been added deliberation of public budgets, supervision of government actions, and full participation in decisions regarding public policies.

The reform of electoral systems and the extension of suffrage have placed on the stage of public and social life, the professional politician, a party member who represents specific interests. The principal interest that became enshrined over the length of the nineteenth century – from the French Revolution to the end of World War I – was to force the acceptance of, respect for, and practice of popular sovereignty as the source of the legitimacy of all power.

Central to an understanding of the evolution of parliaments is the concept of popular sovereignty. It was the new element that entered the political scene in the eighteenth century, whereby monarchic authority – though still enjoying wide support – was no longer accepted as being absolute, nor independent of social support. It found expression in parliamentary democracy that essentially signifies a system in which the government is made up of a nationally elected assembly to which it is accountable. Acceptance of the concept was consolidated during the course of the nineteenth century when the ideal of democracy became associated with the parliamentary system of government.

'Active' parliaments – the importance of which has increased remarkably since 1945 and is still increasing at the onset of the twenty-first century – have taken on a direct responsibility for furthering the public interest. This is in line with a historic trend, initiated in the 1790s, of delegating sovereignty to elected representative bodies. In such parliaments, the house assumes not only the role of deliberating themes of interest to society but also of making decisions relating to public policies stemming from them. Under presidential systems, as is the case of the United States, the powers of the Executive are legitimized by popular vote, independently of parliament. Although this is true in terms of the origin of legitimacy (the ballot), it does not mean that the concrete exercise of power is free of controls. On the other hand, the extension of suffrage and the continuous rate of development of political participation since the 1830s have brought about changes in the exercise of power that have not excluded the presidential systems. Though it may even be possible to govern without parliament – against parliament it is not possible to govern. Though a strong presidential government might tend to ignore collective assemblies, nonetheless, the democratic framework of the state serves to counterbalance the relationship. Parliamentary democracy is an achievement of the Western European States and increasingly of a number of Latin American and former communist Eastern European States. It is also the result achieved by certain nations of the British Commonwealth, which, since becoming independent of Britain, have incorporated the parliamentary system of government. Such is the case in Canada, Australia, India, and New Zealand. Democratic and parliamentary systems are rarer and less stable in Africa, the Middle East, and the Far East.

The expansion of suffrage, resulting in mass democracy and recourse to regular popular participation (formalized through political parties or indirectly through lobbies or special interest groups), have caused parliaments to assume the roles of formulation and assessment of public policies (and of decision making under parliamentary systems of government), particularly in the financial area (through the preparation of the budget and the exercise of control over its execution). The rate at which parliamentary institutions have assumed a leading role in the political process varies from one region to another. In periods of economic expansion or of war, the active role of parliaments may go into retreat, as occurred in the *Belle Epoque* and during World Wars I and II. Under authoritarian regimes, of the left or of the right, it is not uncommon for parliaments to be merely irrelevant decorative trimmings to the institutional architecture (as was the case in Fascist Italy, Nazi Germany, in the communist countries, and under the military dictatorships of Latin America in the twentieth century). Beginning in the 1990s, successful experiences of systems of government centered upon parliaments have been adopted in various regions of the world. In Eastern European countries, the West European parliamentary model of political organization has been widely adopted, though it runs up against the tendency to fall back on a powerful Head of State with a presidential profile that is a legacy of the centralizing tendency of a communist past that lasted from 1945 to 1990. In Latin America, with the restoration of democracy that began in the 1980s, parliaments have taken on importance in a context clearly dominated by the presidential models of the North American type. In Asia, Japan,

and India, active parliaments have been the rule since the late 1940s. In Africa, although practically all countries have parliamentary institutions, the parliamentary model, whether active or deliberative, remains incipient and the role of parliaments largely irrelevant, in a context in which the growth of religious movements strongly affects the neutrality of the parliamentary institution.

Future Prospects

Issues discussed when examining the history of parliaments fall largely into three groups: the external environment; domestic characteristics; and the political characteristics of parliaments. The external environment includes efforts to articulate four trends: the constitutional structure of parliaments, the administrative structure, the (political or electoral) system upon which they are based, and the interest groups with which they must interact. Their domestic characteristics comprise five factors that are decisive for the process of constituting parliaments: their members (their social and professional background, political experience and aspirations, and their degree of commitment to the legislative branch); parliamentary parties; committees; and houses as operational institutions; relations between members of parliament and their constituents as a reflection of social, economic, and cultural structures. The characteristics of their politics open up the possibility of studying parliaments as forums where the repercussions of short-, medium-, and long-term structures are felt and the way in which they reflect the dynamics of political decisions.

There are five principal trends in the historical research on modern parliaments: recovery and systemization of sources; sociological analysis of the composition of parliamentary representation; a prosopographic examination of parliamentary speeches; analysis of the role and impact of parliamentary speeches; and analysis of the role of parliaments in public administration (the formation and control of governments, monitoring and assessment of public policies, and taking of measurements among the voters and public institutions). A great portion of these trends is typically European. In Great Britain and in Germany, for example, recovery of sources is an important approach when placing parliaments within a historical context. The same is true in Brazil, Canada, and Australia. In all these cases, this monumental work has been linked directly to the consolidation of their respective identities over time and to the legitimization of the democratic structures of the States. However, as also occurs in other walks of life, historical research trends evolve.

Not so long ago it was possible to write on the history of parliaments by concentrating solely upon formal texts. Causes and developments would be carefully taken into account, accounts taken down in writing in accordance with the level of detail required, and the consequences for political parties and other significant players in the political processes analyzed. In many of the older texts, an implicit (and sometimes explicit) premise recurring throughout the explanation of the causes and consequences of parliamentary life was that it was possible to chart their progress. History reveals the emergence of parliamentary democracy, as legislation expands the electorate (in accordance with the results of the census, especially in the nineteenth century), to a certain degree making the vote more equal and elections more 'honest.' It was perfectly possible to explore democracy through reference to certain key political dates in each country. Thus the British system came to be regarded as a paradigm by others, as it ensures mechanisms that guarantee the peaceful transfer of power.

Such emphases have been radically altered. First, historical research, in a more skeptical and less self-confident age, no longer seeks to chart the progress from a smaller to a larger state, not least because society at the end of the twentieth century has become much more ambivalent about the building of progress. Second, because much more emphasis had been devoted to continuity than to change (especially with respect to representative democracy). Third, research efforts (polling) at the constituency level have greatly increased. It is hardly surprising that such work produces revelations that do not support the progressive view. It could be argued that the nature of the political process has undergone changes for the worse, from the viewpoint of the lower classes. The way in which governments manipulate electoral laws and the rules defining constituencies and how majorities are defined (for example, proportional systems, simple majorities, or mixed systems) has become relevant research themes in the field of historical research, the results of which are only recently coming to light.

Furthermore, historians have begun to question the importance of the vote for participation in the political process. Indeed, a well-substantiated demand addressed to the administration is likely to be more effective than heated political speeches supported by a few votes in a legislative body. The parallel with nineteenth-century Brazilian politics (and the process of overthrowing dictatorships in the twentieth century, particularly in Latin America) are cases in point. As O'Gorman and Vernon showed for Great Britain, lack of voter participation has not been an obstacle to political participation. Members of Parliament must take a broad spectrum of interests into account if they wish to remain on good terms with their constituents. The right to vote does not necessarily bring with it the access to political power. The suffragettes of the early twentieth century produced brilliant political propaganda, showing that educated, intelligent women with an interest in public affairs were denied the access to vote, whereas ignorant, vulgar, and drunken men were free to participate in it. In reality, such campaigns had a reach far beyond the mere exercise of the ballot: they were an affirmation of the importance of women in a stable political system.

Interest in electoral policies has been reinforced by detailed studies of elections, supported by long-term statistics. Such statistics have used materials that historians immediately recognize as being prime raw material for such studies. Voter registration records prior to the introduction of the secret ballot in Great Britain in 1872, for example, show who voted for whom. Such surveys make it possible to monitor changes in voting habits and to identify which candidates or parties lost favor with different social groups. The 'social geography' of elections and the 'sociological premises' of a given society thus become important instruments for historical analysis. Historical research brings together both the quantitative and qualitative techniques of the social sciences to obtain relevant results for analysis of parliaments.

Political studies relating directly to social and occupational structures also touch upon two other lines of work carried out over the past 40 years. 'History from below' was in vogue in the 1960s and 1970s, when many researchers began to devote themselves increasingly to social structures. Attempts to discover the origins of the 'working class' and, somewhat later, of the 'middle class' involved deep social analyses. Historians more sensitive to issues of social class admit that political awareness plays a part in the issue. Indeed, class consciousness is related directly to the exercise and pursuit of power and in turn requires the existence of political structures that need to be changed. Nonetheless, in Europe, as of the early nineteenth century, debate on parliamentary reform became enmeshed in discussions on social class and on changes in the 'political culture.'

Another important intellectual development has been the emergence of the 'linguistic turn' that began to influence historians in the 1980s. Detailed studies of language as a vehicle for conveying ideas, conducted by historians, have been inspired by radically new ideas borrowed from literary criticism. The relevance, and even the validity, of such an approach has engendered much debate among historians versed in the empirical tradition. Many are reluctant to accept that language can build its own realities, rather than having been invented to serve economic, social, or cultural needs. Unquestionably, extreme versions of poststructuralism, which claim that a text has no validity except in its own context, undermine any type of historical investigation in that they do not accept the notion of relative importance and suggest that change cannot be explained by intentional 'privilege' attributed to particular parts of historical documents. The 'linguistic turn' causes historians to be even more strict in the control of their premises on parliamentary discourse as a historical source. Language may effectively be used to mold ideas. Studies on demagoguery, populism, and *caudillismo* and their influence upon the formation of parliaments in such countries as Brazil, Mexico, and Argentina, are pioneers in this field. The study of the language used by the Chartist reformers of parliamentary democracy in Great Britain, for example, shows that their real goal was political change.

A third theme relating to the expansion of the democratic process is treated under the term 'progress.' Research shows clearly that, when it comes to political change, progress is neither simple nor linear. Parliamentary history is related to, but not defined by, the history of democratization. 'Democratization' of itself is a highly problematic and contested concept. Nonvoters are not necessarily excluded from politics. No parliamentary reform ever 'grants power' to another social group – at any rate, not directly. Women do not all of a sudden hold power simply as a consequence of a scrap of paper called a 'law.' Current research trends show that the law is more likely to ratify a political order already in place than to introduce sweeping change. The development of supranational parliaments in the second half of the twentieth century (the European Union, Mercosur) provides an entirely new field, into which investigative research is just beginning.

Historians have become more involved with continuities. Much of the historical research carried out in the 1980s and 1990s was accompanied by warnings about the dangers of economic reductionism, or of any other type of reductionism. However, the determination of historians to attempt to see things 'within their context' has contributed to the clarification of a series of relevant conclusions on the subject of parliamentary reform. They are now more aware that neither the 'top-down' explanations based upon the higher policies of central parliaments, nor the 'bottom-up' approaches that concentrate on extraparliamentary forms of pressure, are of themselves sufficient. The emphasis has swung to the need to understand the intricate interrelations of the complex factors, which created the political culture of the twentieth century and, above all, in the sequel of three major events of contemporary times, the World War II, the fall of the Berlin Wall and the revival of religious militancy. The changing methods and interpretations nonetheless confirm the central role of parliaments in this culture.

Abstract

Talcott Parsons' social theory rivals the 'classic' theories of Karl Marx, Emile Durkheim, and Max Weber in empirical suggestiveness and analytical rigor. His social theory – popularly called action theory, functionalism, and structural–functionalism – evolved through three periods or phases: voluntaristic action, pattern variables, and the AGIL schema. Throughout his career, Parsons endeavored to ground the social sciences against relativism by basing them on analytical distinctions rather than on empirical generalizations or ideal types. In the last two decades of his life, his publications were subjected to increasing criticism, much of it rhetorical and personal. By the late 1980s, a 'neofunctionalism' emerged in the United States and Germany to press for a reconsideration of Parsons' publications and for new empirical applications of his theory.

From the late 1940s to the mid-1960s, Talcott Parsons was the single most influential social theorist in the world. A developer of what is now popularly called 'action theory,' 'functionalism,' and 'structural–functionalism,' Parsons spent his entire career at Harvard University, which helped considerably in institutionalizing his ideas and also in providing him access to talented graduate students. By the 1950s, his publications became a major part of what was literally a 'common curriculum' for graduate students in all major sociology departments – as well as in many of the best political science departments. By being institutionalized in this way, Parsons' publications elevated the rigor of American graduate training in sociology in particular. More than anyone else, he also defined the 'classic' theoretical tradition for sociology as a discipline and then added a more abstract, arguably more conceptually sophisticated contemporary rival to it. With this, he raised the bar for social theory worldwide, from Germany, France, and Great Britain to Japan and even the former Soviet Union. A strong case can be made today that every major social theory since the mid-1960s has been developed in direct or indirect dialog with Parsons' functionalism.

Having become literally an icon in the discipline in the first three decades of his career, in the last two decades he attracted a considerable share of the iconoclasm that more generally characterized the student movement and academia of the late 1960s and early 1970s. Parsons was subject across two decades to far greater criticism than that directed to any other theorist of his generation or since. Given the tenor of the times, most criticisms were rhetorical, often personal. Today, they leave a strong impression that few critics had bothered to read his works with the care typically afforded to basic empirical studies, let alone with the rigor and dispassion that any complicated social theory demands. Yet, the cumulative effect of the broadsides he received in the late 1960s and early 1970s was to leave the collective memory of the discipline with an understanding of Parsonian functionalism that is difficult to reconcile with often-repeated, explicitly stated positions in his publications. What Parsons endeavored to accomplish in his day, providing the social sciences with a common language, and how he went about accomplishing it, developing a 'conceptual framework' comprising analytical distinctions, now eludes the discipline's collective memory.

Talcott Parsons was born on 13 December 1902 in Colorado Springs, the youngest of six children of Edward S. Parsons, a congregational minister and college administrator, and Mary Augusta Ingersoll Parsons, a housewife and active suffragist (on biographical details, I rely primarily on Nielsen, 1991). Both parents were New England WASPs who traced their ancestry to mid-eighteenth century settlers, Mary to theologian Jonathan Edwards. A graduate of Yale Divinity School, Edward Parsons holds fundamentalist views of Christianity but leftist views in politics, particularly regarding the issue of economic inequality. He is an active participant in the Social Gospel movement that supported organized labor. Both parents inculcate into Talcott and his older siblings the importance of finding a mission in life and then pursuing it assiduously. Many observers comment later on the mature Talcott's remarkable energy and perseverance – including on the final 2 days of his life in Munich in 1979. He published over 150 sole-authored articles and 14 books or collections.

In 1917, the Trustees of Colorado College force Edward to resign as Dean after he supports two women who charged the College's President with sexual harassment. The family then moves to New York City where Talcott enters Horace Mann High School, a laboratory school for boys operated by Teacher's College of Columbia University. Talcott earns an undergraduate degree at Amherst College (as had his father and two older brothers) from 1920 to 1924. At the time Amherst was also an experimental, progressive school. Parsons at first focuses on biology and chemistry but in his junior year becomes 'converted' to the social sciences under the influence of an unorthodox institutional economist, Walton Hamilton.

Parsons' graduate training was remarkably brief: one academic year (1924–25) at the London School of Economics (LSE) as a nondegree candidate, then another (1925–26) as a degree candidate at Heidelberg University. At LSE, Parsons was influenced by Morris Ginsberg, L.T. Hobhouse, and the methodological functionalism of anthropologist Bronislaw Malinowski – as well as by fellow-student E. E. Evans-Pritchard. Parsons also met his future wife and mother of three children,

Helen Banerott Walker, a Bryn Mawr College student studying banking. Her family of conservative white- and blue-collar workers consider Talcott a leftist, a 'pinky.' At Heidelberg, Parsons first learned of the recently deceased German social theorist Max Weber and discussed his work with his wife Marianne, his younger brother Alfred, and Alexander von Schelting. Taking coursework from Edgar Salin and Emil Lederer (on economics), Karl Mannheim (a friend of Georg Lukacs) and Karl Jaspers (on Kant), Parsons selected how sociology and economics differ in portraying 'capitalism' as his dissertation topic.

During his year at Heidelberg, Parsons was offered a 1-year teaching appointment at Amherst in the Economics Department which also allowed him to teach an independent course in sociology. In 1927, Parsons was offered an instructorship in economics at Harvard, thus beginning a life-long career there. Harvard's Department of Sociology was a relative latecomer in the discipline, beginning in the fall 1931 under the chairmanship of Pitrim Sorokin, a 42-year-old emigre from Russia recruited from University of Minnesota. Parsons, then 29, was appointed as an instructor. Disagreements and misunderstanding between the two theorists became common knowledge in the Department and across the University. Yet, throughout Parsons' career, both critics and proponents often commented on his low-key demeanor when grappling with ideas and interacting with colleagues and students. It is difficult to find accounts of him being particularly effusive, let alone dominating. A short, stocky, already balding young man who sports a mustache and always smokes cigarettes, critics also comment often on his charm when interacting with other major national and international academicians at Harvard, in the American government, and overseas.

During his earliest years at Harvard, Parsons was impressed with philosopher Alfred North Whitehead and his notion of the 'fallacy of misplaced concreteness.' Consistent with Kant, Whitehead held that scientists apprehend 'reality' or scientific 'truth' only through analytical distinctions, not more immediately – whether experientially or directly through empirical findings. A few years later in correspondence with phenomenologist Alfred Schutz from 1940 to 1941, Parsons defended the notion of 'analytical realism' – as opposed to ontological realism or empirical realism – against Schutz's position that social scientists can somehow gain more direct access to the 'lifeworld' of their subjects of study (Grathoff, 1978).

By contrast to Schutz and then also to ethnographers at University of Chicago and American empirical researchers more generally, Parsons endeavored across his 50-year career to identify the most irreducible analytical distinctions unique to sociology, the scientific study of social life. In pursuing this project, Parsons arrived at three successive 'theoretical syntheses' and along the way trains four remarkably talented and productive cohorts of graduate students. All three of Parsons' theories, which he called 'frameworks of concepts,' involve a 'functionalist' approach to the study of social life. This is an approach much maligned today, and yet a basic premise of functionalism is hardly controversial. Any social scientist who poses the following question is operating within a functionalist approach: What is the relationship, if any, between the substantive area of social life I am studying and the direction of social change? Here, then, is a common ground shared by critical theorists and Parsonian functionalists but not by more historicist researchers, those who study particular events or periods in isolation and are loathe to identify any direction of social change.

While exceedingly abstract and complex, there are two ways to grasp the significance of Parsons' publications across his career. In general, he endeavored to account for the place and purpose of norms in maintaining social order both historically and cross-nationally. More particularly, he endeavored to account for the place and larger significance of professions, a unique set of occupations, in contemporary societies. Professions are a pivotal subject for sociological inquiry because they are important nongovernmental bodies in all modern societies. Yet, their prestige or status in any society hinges as much on whether they are valued culturally, supported by generally recognized social norms, and centrally situated in a social structure as on whether practicing professionals compete effectively in self-regulating markets. In all modern societies, professionals are simultaneously driven by economic pressures to maximize profits, like other workers, and also by normative pressures to conform to certain extraeconomic standards of conduct that typically do not bind most other workers. Parsons was interested in accounting at a theoretical level for the rise, evolution, and institutionalization of these extraeconomic restraints on self-interested behavior, and then also to explore whether and how they contribute to social order.

In his earliest publications, from the 1920s to the mid-1940s, Parsons approached professions by first distinguishing their behavior from that of economic enterprises, on one side, and religious organizations, on the other. Corporate managers and shareholders tend to act in strictly utilitarian or market-mimicking ways as they endeavor to maximize either growth or profit, a quantitative end that can be recognized interpersonally. Clerics and religious believers, however, tend to exhibit ritualistic fidelity to norms as they – presumably – seek spiritual salvation. This is a qualitative end that is transcendental or metaphysical; as such, its attainment is a matter of faith, not something that can be recognized interpersonally. Professionals, Parsons held, also exhibit fidelity to norms, but more 'voluntaristically.' They do not act in strictly market-mimicking ways, but they also do not conform to norms ritualistically with any transcendental end in view. Rather, they exhibit fidelity to norms as a means to attain qualitative ends that are worldly or empirical, and thus capable of being recognized interpersonally – such as their patients' physical or mental health, or their clients' legal innocence, or scientific truth.

Parsons came to appreciate the significance of 'voluntaristic action' after a careful reading of two economic theorists, Alfred Marshall and Vilfredo Pareto, and two social theorists, Emile Durkheim and Max Weber. This reading forms the core of *The Structure of Social Action* (1937) which, along with Parsons's, 1930 translation of Weber's *The Protestant Ethic and the Spirit of Capitalism*, established Weber and Durkheim as two of the new discipline's 'classic' theorists. During the 1930s, Parsons trained a first cohort of graduate students in the classics and his own theory of 'voluntaristic action,' including: Robert Merton, Kingsley Davis, John and Mathilda

Riley, Edward Devereux, Marion Levy, Wilbert Moore, and Florence Kluckhohn (along with Edward Hartshorne who was killed by a sniper while on active service in postwar Germany).

In spring 1944, Parsons was promoted to full professor and the chairmanship. By January 1946, he transformed the Department of Sociology into the Department of Social Relations, with the explicit aim of linking structural and social psychological approaches in the scientific study of social life. In the same year, Parsons also began formal training in psychoanalysis as a Class C candidate at the Boston Psychoanalytic Institute. He had been lecturing informally on Freud since fall 1938.

As Parsons assumed his leadership role in Harvard's Department, his theory went through a brief mid-career change from the late 1940s to the mid-1950s as he considered findings from Robert Bales's study of small groups. Parsons began thinking about professions (and how to identify norms in social life more generally) in terms of six basic decisions that people performing any role or task either make explicitly or have imposed on them by cultural values, institutionalized norms, or social structures. For example, certain roles (including those performed by professionals) mandate treating others (clients or patients) in universalistic ways. By contrast, other roles (including those performed by parents) encourage more particularistic treatment of others (children). Parsons called these decisions and requirements 'pattern variables.' By his account, researchers can use six such variable-pairs (1) to distinguish professions from other occupations and (2) to identify changes in the behavior of professions both historically and cross-nationally. Parsons' major publications during this period are a collection, *Essays in Sociological Theory Pure and Applied* (1949), and three monographs: *The Social System* (1951), *Towards a General Theory of Action* (1951, with Shils), and *Working Papers in the Theory of Action* (1953, with Robert Bales and Edward Shils).

During this period, Parsons trained a second cohort of graduate students in the pattern variables, including: Bernard Barber, Harry Johnson, Robin Williams, Jr., Jesse Pitts, Harold Garfinkel, Francis Sutton, and Robert Bales. More generally, as part of the buoyancy and optimism that pervaded the US after the war, many sociology departments reevaluate their curricula. The discipline is open collectively to receiving a new theoretical synthesis, and Parsons' notion of pattern variables, while preliminary and as it turned out fleeting, is a prime candidate. Another is Robert Merton's notion of 'middle range theory,' an idea he first proposed at the annual meeting of the then American Sociological Society in 1947 in opposition to Parsons' 'general theory.'

Finally, beginning slowly in the mid-1950s and then with more rapid developments from the early 1960s to the end of his career, Parsons approached professions within what he called the 'AGIL schema.' This is Parsons' single most significant contribution to social theory. During his transition from the pattern variables to the AGIL schema, Parsons' publications, lectures, and presentations create an unusually kinetic intellectual excitement among collaborators and graduate students. Everyone working in his circle operated with a palpable sense that social theory is in the midst of a fundamental breakthrough, a sense that American sociology has not witnessed since.

This transition period to Parsons' mature social theory is marked in particular by *Economy and Society* (1956, with Neil Smelser), and Parsons' training of a third cohort of graduate students, including: Albert Cohen, Renee Fox, Joseph Berger, Norman Birnbaum, Neil Smelser, James Olds, Jackson Toby, and Miriam Johnson. In addition, many earlier graduate students whose training had been interrupted by wartime service returned to Harvard. Talented undergraduates who come into contact with Parsons during this period include Robert Bellah and Charles Tilly. Also in transition during this period is the leadership of sociology at Harvard. Parsons resigns as chair of the Department of Social Relations in 1956, and within the next 2 years learns that he has diabetes. Sorokin retires in 1959.

From 1956 to 1961, Lewis Coser and Dennis Wrong in the US, David Lockwood in Great Britain, and Ralf Dahrendorf in Germany challenged Parsons' functionalism in relatively measured tones, but with uneven rigor. They were also shooting at a moving target in that Parsons was developing his mature social theory. The high-point of scholarly criticism during this period comes with a collection of essays by philosophers and sociologists edited by Max Black, to which Parsons responded with a long concluding chapter. In April 1964, Parsons was a central figure at a famous session of the German Sociology Association in Heidelberg devoted to reconsidering Max Weber's contributions. He found himself at odds with Frankfurt School critical theorists, most notably the young Jürgen Habermas and the more established Max Horkheimer and Herbert Marcuse (see Stammer, 1965/1972 for a collection of these exchanges).

From this point forward, criticisms of Parsons become harsher, more personal, and ideological than analytical and scholarly. Parsons was attacked, particularly in the US, for: his religious background, his WASP ethnic and cultural heritage, his writing style, his amazing productivity, his putatively strategic rather than scholarly decision to make sociology as rigorous conceptually as economics, his putative mistranslation of Weber, the putative conservative nature of his own family life including his putative responsibility for his daughter's suicide (in June 1964, 2 weeks after the Heidelberg debate), his putative political conservatism, and his putative general obeisance to 'American capitalism' or 'the establishment.'

Parsons unveiled the AGIL schema explicitly in 1963, with major articles on the concepts of power and influence, and then in 1964, with his first statement about 'evolutionary universals' (see the Turner, 1999 collection for the 1964 article and references to the others). As fully developed, the AGIL schema isolates analytically those aspects of behavior in any role or position that contribute, respectively, to each of four general social 'functions': economic efficiency ('adaptation'), administrative effectiveness ('goal attainment'), fidelity to social norms ('integration'), and fidelity to cultural values or a society's most basic institutional arrangements ('latency'). Parsons also proposed that four 'media of interchange' circulate between these analytical subsystems – money, power, influence, and value commitments – thereby bringing a certain orderliness or predictability to the whole. He added notions of 'systems-theory,' 'pattern maintenance,' and 'hierarchy of control' to this basic four-function breakdown of social life.

In 1973, Parsons and Platt published what is arguably his most important single work since 1937, *The American University*. In this work, Parsons rethinks his approach to professions by incorporating two major points into his social theory. First, he proposes that professions and sites of professional practice (such as universities, hospitals, and research institutes) are organized in a 'collegial form,' not in a bureaucratic form or a democratic form. Second, he proposes that professions are distinguished from other occupations by their members' willingness to bear 'fiduciary responsibilities' to clients and the larger society. These two points provide the foundations for an account of the place and purpose of professions in contemporary societies that differs radically from any effort, whether by rational choice theorists or social critics on the left, to treat the professions analytically as interchangeable with other occupations or other corporate entities. By 1973, however, the collective memory of the discipline is so dominated by criticisms of the AGIL schema that this major work, arguably Parsons' single most important substantive contribution to social theory, goes largely unread by critics and proponents alike.

Through the 1960s and 1970s, Parsons trained a fourth and final cohort of graduate students in the AGIL schema and related theoretical developments, including: Victor Lidz, Jan Loubser, Leon Mayhew, Rainer Baum, Dean Gerstein, John Akula, and Willy DeCramer. Parsons also influences undergraduate Jeffrey Alexander. Only in the mid-1970s, a few years before his death, did Parsons begin methodically to respond to at least a few criticisms of his work, most notably the informed analyses of Bershady (1973) and Warner (1978). Bershady's *Ideology and Social Knowledge* in particular marks a major sea change in commentary on Parsons' works. Bershady is the first to draw attention to Parsons' effort to ground the social sciences against relativism with analytical concepts. More than anyone else Bershady appreciates that Parsons pitched his social theory at an unusually abstract level of analysis because he sought literally a common language for the social sciences. Prior to Bershady, both proponents and critics generally failed to convey the power and sweep of Parsons' social theory in form, its aspiration to unite the social sciences. Parsons' project was essentially to give structuralists and symbolic interactionists the means, the common language, by which to demonstrate to each other the central import of their respective findings.

Parsons demonstrated his capacity to 'translate' others' findings and ideas in his own scholarship. He coauthored, team-taught, or otherwise collaborated closely with a remarkable range of theorists and researchers across disciplines, including: Edward Shils, Joseph Schumpeter, Samuel Stouffer, Florence Kluckhohn, Robert F. Bales, James Olds, Morris Zelditch, Philip Slater, Neil Smelser, Lon Fuller, Kaspar Naegele, Jesse Pitts, Winston White, S.N. Eisenstadt, Robert Bellah, Victor Lidz, Gerald Platt, Edward Laumann, Erwin Scheuch, Andrew Effrat, Mark Gould, and Dean Gerstein. In addition, he engaged in private and public correspondence and debates with Frank Knight, Crane Brinton, Robert Bierstedt, Albert Blumenthal, Alfred Schutz, Chester Barnard, Philip Selznick, Eric Voegelin, Robert Merton, Kenneth Boulding, C. Wright Mills, Robert Bellah, Bennett Berger, David Riesman, Jurgen Habermas, Herbert Marcuse, Max Horkheimer, and Ernst Mayr. Finally, an impressive set of scholars were influenced heavily by Parsons himself, his students, or his theory (some of whom also influence Parsons and his students): Niklas Luhmann, Seymour Martin Lipset, Amitai Etzioni, Robert Marsh, Daniel Bell, Joseph Ben-David, Benjamin Nelson, Gabriel Almond, James S. Coleman, Karl Deutsch, David Apter, Lucian Pye, Sidney Verba, Chalmers Johnson, S.N. Eisenstadt, Ken'ichi Tominaga (Japan's leading postwar sociologist), Lawrence Brownstein, Martin Martel, Adrian Hayes, and Frank Lechner.

Parsons and Helen traveled frequently in the 1970s, including three separate trips to Japan. In early May 1979 they returned to Heidelberg, then proceeded to Munich, on the occasion of the fiftieth anniversary of Talcott's degree from Heidelberg. After Parsons' typical full day of presentations and scholarly exchanges, including a lecture on 'The Declining Significance of Social Class' attended by host Horst Helle as well as Jurgen Habermas, Niklas Luhmann, Richard Munch, and Wolfgang Schluchter, Parsons died of a stroke in the early hours of May 8. At a memorial service 10 days later in Harvard Chapel, Victor Lidz notes in eulogy: "No sociologist of recent times has had to endure more bitter criticism than Talcott. Although a passionate man, Talcott bore criticism with equanimity as well as courage. Not daunted by even sweeping attack, he held to his own program of research and writing. Moreover, adhering to principles of value-freedom, he declined to reciprocate ideological criticism. He dealt with criticisms, always, as technical matters within the domain of social scientific theory" (Nielsen, 1991).

Parsons' critics inadvertently encouraged the fragmentation of research and theory in sociology and the social sciences that Parsons endeavored to prevent. Today, in the absence of any shared framework of analytical concepts, social scientists routinely talk past each other, as opposed to revealing to each other the general importance of their research findings and theoretical developments. Parsons's 'general theory' has given way not to a finite set of readily identifiable theories of the 'middle range,' as Robert Merton anticipated in 1949, but rather to an ever more finely grained cacophony of research specialties. This trend is then recapitulated, and accelerated, by ongoing changes in graduate training. Graduate students are trained more and more narrowly, and their required survey courses in social theory hardly encourage them to move beyond any research specialty. If there is any 'common language' in the social sciences today, it is that of research methods. But even here there is more internal division among methodologists than they often wish to acknowledge.

In support of Habermas' point that we can expect any new theoretical development in the social sciences to respond directly or indirectly to Parsons' functionalism, French social theorist Pierre Bourdieu in many regards today recapitulates Parsons' AGIL schema. He identifies two poles within what he calls 'fields of power' – the economic field and the field of cultural production – and then distinguishes four fields in between: politics, the higher civil service, the professions, and the university (Bourdieu, 1989/1996). The major difference with Parsons is that the French theorist's categories are more directly descriptive, less analytically rigorous. As a result, it is not clear on what basis he is distinguishing fields, why there are six fields of power rather than four or eight, or on what basis

researchers may categorize particular groups or activities as components of one field or another.

By the early 1980s, a new generation of social theorists, including members of Parsons' last cohort of graduate and undergraduate students at Harvard, initiated the effort to have Parsons' publications reconsidered on scholarly grounds. Led initially by Munch (1981) in Germany and Alexander (1983, 1985) in the US, today's 'neofunctionalism' finds support from theorists whose political positions range from radical left to liberal reformist to conservative republican (see the collections edited by Hamilton, 1992; Colomy, 1990). What they share, with Parsons himself, are two general principles (which Alexander, 1988 now explicitly rejects). One is that it is vitally important to the social sciences to continue Parsons' effort to ground social theory on the basic analytical distinctions of the AGIL schema rather than to rely more directly on descriptive concepts (whether empirical generalizations or ideal types). The other principle is that it is incumbent today to demonstrate the empirical potential of Parsonian functionalism, to identify lines of empirical inquiry that this social theory uniquely presents to view (Sciulli, 1992). A strong case can be made that Parsons' social theory has been mined only superficially (Takagi, 1992). An equally strong case can be made that theorists and researchers today can draw fruitfully on Parsons' basic AGIL schema, and then the first set of subdivisions he drew within each 'function,' but that they need not follow Parsons' effort to draw further distinctions within each subdivision (Mouzelis, 1995).

Social theorists outside the US today who support the Parsonian tradition, even if critical of certain parts of it, include: Munch, Hans Joas, Uta Gerhardt, Horst Helle, and Harald Wenzel in Germany; Helmut Staubmann in Austria; Jens Kaalhauge Nielsen in Denmark; Pierpaolo Donati, Andrea Maccarini, Matteo Bortolini, and Riccardo Prandini in Italy; Ken'ichi Tominaga, Kiyomitsu Yui, and Kazuyoshi Takagi in Japan; and Nicos Mouzelis, Bryan Turner, and Jeremy Tanner in Great Britain.

Editor's Note

Parsons' work, theories, and influence continue to be discussed in contemporary social science discourse. He has been identified as one of the fifty most important social theorists in the history of sociology in Scott (2007). His continuing relevance to economic sociology is discussed in Tittenbrun (2014) and Swedberg (2014) discusses the relationship and mutual influence between Parsons and his contemporaneous Harvard colleague, the economist Joseph Schumpeter. Other current commentators still turn to Parsons as a theorist of community (Lidz, 2014), a complexity theorist (Zwick, 2011), a sociologist of religion (Vanderstraeten, 2012), an analyst of the 'sick role' (Varul, 2010), and a great deal more. His works are still being reprinted decades after his death in 1979 including *The Social System*, which was reissued by Routledge in 2013. Book-length exegeses of his thinking and contributions to social theory continue to proliferate (e.g., Gerhardt, 2011).

Partial Orders

This article is reproduced from the previous edition, volume 16, pp. 11068–11073, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

The article expounds the definition and basic properties of partially ordered sets. Related notions such as quasiorders, weak, and linear orders are introduced. Semiorders and interval orders are discussed with particular emphasis on their numerical representations. The order theoretic and algebraic properties of lattices are summarized. The question of the possibility of linear extensions of posets is answered by presenting Szpilrajn's theorem. This topic leads to the concept of order dimension. The discussion of the 'MacNeille completion' of an order ends the article.

The idea of ordering captures a basic faculty of the human mind: to decide for two given elements from a set of objects which one 'dominates' the other with respect to an attribute of interest, or, alternatively, which one is 'preferred' to the other.

Formally, a partially ordered set (a poset for short) consists of a pair $(P, \leq)$ where P is a nonempty set and $\leq$ a binary relation on P satisfying for all $x, y, z \in P$:

1. reflexivity: $x \leq x$,
2. asymmetry: $x \leq y$ and $y \leq x$ implies $x = y$,
3. transitivity: $x \leq y$ and $y \leq z$ implies $x \leq z$.

Transitivity is, in a sense, the most important property; it is shared by all variants of order relations, though it might be a consequence of other conditions. However, asymmetry also contributes in an essential way to the meaning of a partial order. Reflexivity, on the contrary, is merely a matter of taste or convenience. In some cases its opposite, irreflexivity, is postulated. Such an order is called *strict*. If the asymmetry condition is replaced by symmetry, i.e., for all $x, y \in Px \leq y$ implies $y \leq x$, then the resulting structure is an equivalence relation which lacks the interpretation of 'dominance' or 'preference.' Such a structure is more akin to classification or grouping with respect to similarity.

Related Notions and Diagrams

Sometimes asymmetry is simply dropped from the conditions. A relation satisfying reflexivity and transitivity is called a quasiorder. The investigation of quasiorders can be split into the respective properties of a partial order and an equivalence relation in the following way: Let $(Q, \lesssim)$ denote a quasiorder. Define $x \sim y$ if $x \lesssim y$ and $y \lesssim x$ both hold true. Then it is readily shown that $\sim$ is an equivalence relation on Q. Let P be the set of equivalence classes and define for $p, q \in P$ the relation $\leq$ by $p \leq q$ if $x \lesssim y$ for some $x \in p$ and $y \in q$. Then, one demonstrates two things: first, that the definition of $\leq$ is independent of the particular elements $x \in p$ and $y \in q$; and second, that $(P, \leq)$ is a poset. Thus, the 'dominance-aspect' of a quasiorder is contained in $\leq$, and its 'classification-aspect' is hidden in $\sim$.

One property of an intuitive meaning of dominance is not captured in the notion of a partial order: the idea that any two elements can be compared with respect to $\leq$. The defining conditions of a poset do not imply connectivity, i.e.,

$$x \leq y \text{ or } y \leq x \text{ for all } x, y \in P.$$

(Note: often this property is called 'completeness,' but later in this article another notion of completeness is introduced.) If connectivity is added to the properties of a partial order $(P, \leq)$, then $\leq$ is called a linear or total order. A quasiorder satisfying connectivity is called a weak order. Applying the above procedure on a weak order results in a linear order on the equivalence classes of the weak order.

There is a tendency to associate the property of connectivity automatically with an order given in some field of application, e.g., if one rank orders stimuli or subjects. Doing this amounts to representing the order numerically, i.e., to assuming a function

$$f : P \to \mathbb{R} \text{ such that } x \leq y \text{ if } (x) \leq f(y). \qquad [1]$$

If such a representation is possible, the order is necessarily a weak order. However, in social science, numerical representations are used widely even for orders which cannot easily be justified to be connected. For example, if the items of an achievement test are 'Rasch-scaled' (see the discussion following eqn. [3]), a difficulty coefficient is attached to each item. This numerical scale orders the items weakly and ascribes the often made observation that subjects solve a difficult item correctly and fail at an easier one to influences of chance and error. This interpretation appears so obvious that its proponents tend to overlook the *petitio principii* which it entails, that the difficulty of an item is defined by the numerical parameter, whereas the weak ordering of the items according to a material notion of difficulty is an empirical property which will in many cases not be fulfilled.

For example, an expert judging this might well regard some items as incomparable. In such a situation a partial- (or quasi-) ordering, which allows for incomparable items, is more flexible. Thus, the assignment of numerical values, albeit ubiquitous in psychological tests, restricts drastically the range of possible models. Even partial orders can be too restrictive because transitivity is also a strong condition. The theory of knowledge spaces takes account of this aspect (*see* Cognition: Knowledge Spaces for a deeper treatment of these issues).

Figure 1 The forbidden substructures of a semiorder.

The most convenient way of representing a poset is by its (*Hasse*) *diagram* (see Figures 1 and 2). To construct it, one first defines $x < y$, in words 'y covers x,' to mean: $x < z \leq y$ implies $z = y$. Next, one draws a graph in which the vertices correspond to the elements of P, two elements are connected by an edge if one of them covers the other, and furthermore the covering element is placed above the horizontal line determined by the covered element. Hasse diagrams are easy to draw and are of great help in theoretical considerations as well as in interpreting empirical findings.

Special Classes of Orders

There are numerous specializations, that is, additions of further properties, such that the resulting structure is something in between a poset and a linear order. In this section, two classes are considered which have useful numerical representations, although not the strong one of eqn. [1]. The third specialization considered here, namely lattices, is important because it tends to bridge the gap between ordering relations and algebraic operations.

Semiorders

In psychophysics one has to deal with the phenomenon of subliminal changes in intensity of physical stimuli. One stimulus may be (physically) slightly more intense than another, but a subject does not perceive the difference. For example, one might imagine a coffeetester confronted with an extended series of cups of coffee, each with one more grain of sugar than its immediate predecessor. He/she will probably not notice the difference in taste between successive cups, but surely the difference between the first and the last cup will be clearly noticeable. In other words, indifference with respect to $\leq$ is not transitive. Similar observations can be made in decision theory and other branches of psychology. One way of describing such facts is to introduce sensory thresholds, thereby creating a scaling problem where one wants to scale both the subjective intensity and the magnitude of the threshold. Luce (1956) considered two conditions which seem plausible in this context (P is the set of stimuli and $x \leq y$ denotes the observation x is less intense than y):

$$\text{(S1)} \quad \text{If } x \leq y \text{ and } u \leq v, \text{ then } x \leq v \text{ or } u \leq y.$$

$$\text{(S2)} \quad \text{If } x \leq y \leq z \text{ and } W \in P, \text{ then } W \leq z \text{ on } x \leq W.$$

One easily shows that $(P, \leq)$ is a quasiorder, i.e., without losing generality, one can assume that it is a partial order. Condition (S1) says that it does not contain Figure 1(a) as a suborder. Similarly, condition (S2) is equivalent to the fact that it does not contain Figure 1(b) as a suborder.

From the viewpoint of measurement the most important property of semiorders is the possibility of a numerical representation with a constant threshold. More precisely, one can show that for a finite semiorder $(P, \leq)$ there is a function f

$$f : P \to \mathbb{R} : \text{ such that } x < y \text{ if } f(x) + 1 < f(y). \qquad [2]$$

The condition of finiteness is far too restrictive for eqn. [2], but without further restrictions it does not obtain. The height of the threshold is arbitrary, that is, the number one in eqn. [2] can be replaced by any other positive number (with a rescaled f). More on this kind of representation theorem can be found in Roberts (1979: Chap. 6.1) or Suppes et al. (1989: Chap. 16). Clearly, the converse of this theorem is true: a structure with a representation, eqn. [2] is necessarily a semiorder.

Although the semiorder concept seems to have its origin in the psychological context of the possibility of measurement of subjective intensity described above, it is now a well-established notion in the mathematical theory of posets and several remarkable results are connected with it. Some of them are mentioned in the following text.

Interval Orders

A structure satisfying only condition (S1) but not necessarily (S2) is called an interval order. This notion derives from the

Figure 2 Lattices (b, c, e) and non-lattices (a, d).

numerical representation which is characteristic of this kind of order. Each element can be represented by an interval on the real line and $x < y$ or $y < x$ is tantamount to the nonoverlapping of the respective intervals. Put another way, a scale value and a threshold are attached to each element, but the height of the threshold can vary in contrast to eqn. [2]. The reader will find many interesting properties and proofs in Fishburn (1985).

Historically, it is of interest that, although the representation theorem is due to Fishburn (1970), the investigation of this structure goes back to papers of Norbert Wiener, early, in the twentieth century. What is even more remarkable is that in this work he mentioned possible applications in experimental psychology (see Fishburn and Monjardet, 1992).

The theory of interval orders has applications in archeology in connection with the seriation problem. In this case P is a set of artifacts, each element of which was some time in use. From excavations in various historical sites it is known for any two artifacts whether the period of use of one follows that of another with or without overlap. If this relation satisfies (S1) then, by the interval order representation theorem, it follows that it is possible to assign a time interval to each artifact, preserving the empirical observations.

A related notion is that of a biorder. The primitives of a biorder consist of two sets P and Q and a relation ρ between P and Q, i.e., a subset $\rho \subseteq P \times Q$ satisfying for all $x, y \in P$ and $u, v \in Q$

$$x\rho u,\ y\rho v,\ \text{implies } x\rho v \text{ or } y\rho u. \qquad [3]$$

To understand this condition, it is helpful to think of P as a set of subjects and of Q as the items of an achievement test. $x\rho u$ means 'subject x fails to solve item u.' The premise of eqn. [3] says that x fails u and y fails u: if one assumes that x solves v correctly, then y has to fail u. With this interpretation, the biorder concept is the basis of Guttman scaling. Probabilistic modifications of it underly Rasch scaling, which is well-established in the theory of psychological tests. Thus, with the biorder condition eqn. [3], a testable property is formulated which, when satisfied, justifies a numerical difficulty value for items because a numerical representation of a biorder consists of two functions $f : P \to \mathbb{R}$ and $g : Q \to \mathbb{R}$ such that:

$$x\rho u \text{ if } f(x) < g(y).$$

This, in turn, implies eqn. [3]. In the terminology of the above interpretation of a biorder $f(x)$ is the ability of subject x and $g(u)$ is the difficulty of item u. If in a biorder, the two sets coincide, $P = Q$, then eqn. [3] reduces to (S1), i.e., the structure is an interval order.

Lattices

In a partial order $(P, \leq)$ subsets of P may or may not have upper or lower bounds, where upper bounds are elements which dominate all elements of the subset and lower bounds are elements which are dominated by all its elements. If each two-element subset has a unique smallest upper bound – called the supremum – and a unique greatest lower bound – called the infimum – then the structure is called a lattice. The infimum of x and y is denoted by $x \wedge y$ and the supremum by $x \vee y$. Examples of lattices and nonlattices are given in **Figure 2**.

Further examples are the power set of a set ordered by set inclusion, any subset of the reals naturally ordered, and the natural numbers $\{1,2,3, \ldots\}$ ordered by divisibility, i.e., $m \leq n$ if m divides n. In the last example, the least common multiple and the greatest common divisor are the supremum and the infimum, respectively. It follows easily by induction that any finite subset of a lattice P has an infimum and a supremum. However, infinite subsets do not necessarily have this property. If all subsets of P have it, then the lattice is called complete. Thus, finite lattices are always complete, but the rationals with the natural ordering are not. The question of completion of lattices similar to the construction of the reals by Dedekind cuts is discussed in Section Embeddability and Completion of Orders.

There is a more algebraic way of characterizing lattices, where infimum and supremum are regarded as binary operations on P:

Theorem 1 Let $(P, \leq)$ be a lattice. Then for all $x, y, z \in P$:

1. $x \vee (y \vee x) = (x \vee y) \vee z$ and $x \wedge (y \wedge z) = (x \wedge y) \wedge z$
2. $x \vee y = y \vee x$ and $x \wedge y = y \wedge x$
3. $x \wedge (x \vee y) = x$ and $x \vee (x \wedge y) = x$

Conversely, if a structure $(P, \vee, \wedge)$ is given with operations $\vee$, $\wedge$ satisfying the conditions (1), (2), and (3), then $\leq$ is defined by

$$x \leq y, \text{ if } x \wedge y = x$$

is a partial order on P such that $(P, \leq)$ is a lattice.

Lattices play an important role in pure and applied mathematics. John von Neumann, one of founders of lattice theory, developed his formulation of quantum mechanics in terms of lattices. Today they are used in many branches of mathematics – for instance, in combinatories, probability theory, logic, and functional analysis. The wide applicability of lattices in technical and social science contexts is best demonstrated by the development of 'concept analysis' by Rudolf Wille (see Ganter and Wille, 1996).

Extension of Orders; Szpilrajn's Theorem

Is it possible to extend a partial order by adding (x, y) or (y, x) to $\leq$, when x and y are incomparable in $\leq$ and at the same time keeping the extended relation a partial order? Is it possible to extend $\leq$ to a linear order in this way? Both questions are answered in the affirmative by the following theorem.

Theorem 2 (Szpilrajn's Theorem) Let $(P, \leq)$ be a poset and $x, y \in P$ such that neither $x \leq y$ nor $y \leq x$. Then there are two linear orders $\leq'$ and $\leq''$, each of which contains $\leq$ as a subset, and such that $x \leq' y$ and $y \leq'' x$.

The proof of this theorem is not difficult for finite P, but entails a set theoretic twist in the infinite case. If x and y are incomparable in $\leq$ then one defines $x \leq' y$, adds all pairs to $\leq'$ which this choice and transitivity forces and goes ahead until no incomparable pairs are left over. The latter step of this argument is a bit of a problem for an infinite P.

Sometimes one can regard a partial order as ensuing from incomplete data collection, incomplete in so far as a linear order can be expected, but the available data give only a part of the full order information. Then the question of a linear

extension is relevant, in particular, one can ask how many additional pairwise comparisons must be performed to obtain the full linear order, which is the most parsimonious way to find such an extension.

For these problems the number of linear extensions is of importance. It was shown by Fishburn and Trotter (1992) that for all partial orders with fixed $|P| = n$ and k pairs in $\leq$ those with a maximal number of linear extensions are semiorders. For $k \leq n$ these semiorders are characterized, but for larger K there seem to remain several unsolved problems.

It can be shown that a linear extension can be found with at most K questions of the form 'is x larger than y,' where K is of the magnitude of the logarithm of the number of linear extensions (see Trotter, 1995 for details). In connection with this problem it seems that a pair x, y for which many extensions with $x \leq y$, as well as many with $y \leq x$ exist is best to investigate first because, whatever the answer, it considerably reduces the number of data which remain to be collected. In this context the so called 1/3–2/3 conjecture was made. It says that each poset which is not a linear order contains a pair (x, y) for which the relative frequency of extensions with $x \leq y$ is between 1/3 and 2/3. This conjecture seems still open. However, bounds are known, e.g., the relative frequency is between 3/11 and 8/11. The proof of this result draws on a geometric inequality and is extremely beautiful. For semiorders the 1/3–2/3 conjecture is true. More on this topic and some of the proofs can be found in Trotter (1995).

Order Dimension

A corollary of Szpilrajn's Theorem is that each partial order is the intersection of its linear extensions. One can ask for the minimal number of linear extensions with this property and regard this number as a measure of complexity of the order. It is called the dimension of $(P, \leq)$.

All orders on three, four, and five elements are two-dimensional (provided they are not linear). There are two orders with six elements of dimension three. One can group the posets in classes of increasing dimension. The semiorders have a dimension less than or equal to three, but the interval orders can have arbitrary large dimension.

One classical result on the dimension is that it is always smaller than or equal to the maximal number of pairwise incomparable elements. For $|P| \geq 4$ ($|P|$ denotes the number of elements in P) the dimension is bounded above by $|P|/2$ and this is the best possible solution. It is an active area of research to find inequalities such as these which relate the dimension to other characteristics of the poset (see Trotter, 1992).

There are other variants of the dimension concept: one can replace linear orders by semiorders (and obtain the semiorder dimension) or by interval orders or by any other class of partial orders. For biorders, see Doignon et al. (1984) and Koppen (1987). These two papers attempt to link this dimension concept to techniques of extracting factors to explain data. In this way, an ordinal factor analysis is outlined. Factor analytic procedures used to be widely spread in social science research, but until now they seem to lack a sound axiomatic foundation. The order theoretic dimension concept can provide a weaker concept of a factor which is, on the other hand, much easier to justify, or empirically to test for adequacy.

Embeddability and Completion of Orders

Sometimes the nonexistence of suprema and infima is a nuisance; just think of the inconvenience caused when a sequence of rational numbers 'converges,' but the limit does not exist (in the rationals). One tries to avoid this situation by embedding a given poset into a complete lattice which contains the original order as a suborder. In contrast to the techniques in Section Extension of Orders; Szpilrajn's Theorem, one adds new elements to P instead of new pairs to $\leq$. Thus, the aim is to find a superstructure which resembles the given order as closely as possible, but which can be handled more conveniently because of the existence of suprema and infima. The prototype of this kind of extension is the time-honored construction of the reals from the rational numbers.

To begin with, some notation must be introduced. For $X \subseteq P$ let:

$$X^{\nabla} := \{y \in P : y \leq x \text{ for all } x \in X\}$$

$$X^{\Delta} := \{y \in P; x \leq y \text{ for all } x \in X\}.$$

Thus X^{∇} is the set of lower bounds of X and X^{Δ} the set of upper bounds of X. The sets $\{x\}^{\nabla}$ and $\{x\}^{\Delta}$ for $x \in P$ are abbreviated by x^{∇} and x^{Δ}, respectively. One simple way of embedding consists of considering

$$\nabla_{(P, \leq)} := \{x^{\nabla}; x \in P\}$$

the so called principal ideal representation. Note that $(\nabla_{(P, \leq)}, \subseteq)$, is a suborder of the complete lattice of the power set, isomorphic to $(P, \leq)$. However, this embedding is not sufficient for the purposes of this section; the superstructure carries too little information from the original one. Therefore, a more parsimonious extension must be constructed.

To this end, a pair (X, Y) is called a MacNeille cut if and only if $X = Y^{\nabla}$ and $Y = X^{\Delta}$. The set of all MacNeille cuts is a better candidate for an embedding. Indeed, one can prove:

Theorem 3 Denote by $C_{(p, \leq)}$ the set of all MacNeille cuts of a partial order $(P, \leq)$. Define for two cuts (X, Y) and (X', Y') the relation

$$(X, Y) \sqsubseteq (X', Y') \text{if } X \subseteq X'.$$

Then $(C_{(p, \leq)}, \sqsubseteq)$ is a complete lattice. Moreover, it is the unique (up to isomorphism) smallest complete lattice which contains the original poset $(P, \leq)$ as a supremum dense subset, i.e., each element of $C_{(p, \leq)}$ is supremum of elements of $(P, \leq)$.

A few remarks should illustrate this theorem. First, the set corresponding to $(P, \leq)$ in $(C_{(p, \leq)}, \sqsubseteq)$ is the set of cuts (x^{∇}, x^{Δ}). Second, if this theorem is applied to the rationals with the usual (linear) order, then the reals with added $\{-\infty\}$ and $\{\infty\}$ result as the MacNeille completion. The element $-\infty$ is the cut $(\emptyset, P)$ while ∞ is the cut $(P, \emptyset)$. Third, although the notion of a complete lattice only bears meaning for infinite base sets P, the MacNeille completion makes sense also for finite posets. **Figure 2(b)** shows the MacNeille completion of (a) and **Figure 2(e)** of (d). Finally, it is worth mentioning that the mappings $X \to X^{\nabla}$ and $X \to X^{\Delta}$ form a pair of functions that are known as a Galois connection. This construction is often used when dealing with posets; it is applicable in other contexts, for example, formal concept analysis (see Ganter and Wille (1996) is based on a Galois connection). In this respect, concept lattices are a generalization of a MacNeille completion.

Participant Observation

Gary Alan Fine, Northwestern University, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Participant observation is one of several qualitative field methodologies used to understand the culture and structure of communities. Used primarily by sociologists, participant observation involves the researcher engaging with the community being examined. This article describes the benefits and drawbacks of this form of ethnographic observation, discussing the historical development of this methodology and describing the variety of roles that a researcher can take in gathering data from a community, and comparisons with other related methodologies. The article concludes by discussing several of the ethical issues (deception, informed consent, confidentiality, and precision of descriptions) that practitioners of this methodology must confront.

Participant observation has been part of the arsenal of methodological techniques employed by social scientists over the past century, notably within the discipline of sociology. This style of data collection involves the active engagement of the researcher with the members of the community that he or she wishes to study, typically as an equal member of the group.

This methodology falls under the general rubric of field research. It is important to recognize that there exist a variety of forms of 'field research,' a range of possibilities that this article will not cover. However, in contrast to the manner in which observational research has traditionally been conducted in anthropology, in sociology much ethnography is based on the assumption that the researcher is not an outsider, but at least nominally a participant in the group being studied. Yet, the line that separates participant observation and other forms of ethnographic observation is uncertain and hazy, and for some scholars the terms 'participant observation' and 'ethnography' have been used as synonyms. Today the term 'ethnography' is the more general of the two, found in wider circulation, such as in the journal titles *Ethnography* and the *Journal of Contemporary Ethnography*.

Since the mid-1970s, there has been a notable increase in the legitimacy of field methodologies within the social sciences. These qualitative, interpretive strategies, once considered 'unscientific,' akin to journalism, have demonstrated their utility in a number of disciplines. Whereas once it was rare to find research grounded on direct observation published in leading journals, this is no longer the case today. That this occurred during a period in which social scientific funding was being decreased is surely no coincidence, as participant observation is not capital intensive, even though it requires much labor on the part of the observer. Although qualitative field methods still do not have equal standing with quantitative methods (especially in fields such as psychology and economics), their growth and acceptance are impressive.

Advantages

Several distinct advantages justify participant observation; among these are the benefits of rich data, validity, *verstehen* (or interpretive understanding), and economy.

Richness

This methodology, in contrast to most research techniques that do not involve personal witnessing, provides for the gathering of rich and detailed data. To investigate *action in situ*, direct observation is essential. When observation is coupled with the questioning of actors about their choices, tied to some measure of active involvement by the researcher, the value of participant observation is known through the detail provided. This style of data collection permits an intense depiction that produces a fullness of understanding.

Validity

A second benefit is analytical validity. Because the observations are of behavior *in situ*, a researcher can rely upon the claim that the findings are close to the scene as it is known by others. If the conclusions drawn from participant observation research are not always reliable, given that other investigators might reach different conclusions, the actions described did occur and descriptions reflect the belief that some aspect of the world, as it 'truly' is, is being described.

Interpretive Understanding

Participant observation supports the demand of Max Weber to produce research that is characterized by *verstehen*, or a personal, knowing understanding. In this way, participant observation with its emphasis on both participation and observation adds to lived knowledge. By directly involving the researcher in the activity, one can understand from an immediate level the dynamics and motivations of behavior. The observer crossed the boundary between outsider and insider. While research projects differ significantly on this dimension of direct experience, involvement has advantages for a *verstende* analysis that other approaches cannot match.

Economy

Participant observation research is typically inexpensive. While this research strategy is labor intensive, it is not as capital intensive as techniques such as survey research or experimentation. In many cases, the researcher works alone and, as

a result, can set the terms of his or her own involvement. Increasingly, however, team research projects are used to collect data, and in these cases wages and benefits for hired observers may involve considerable costs, even if they multiply the number of sites observed. Yet, in the traditional participant observation project, the key resource necessary is a technology for inscribing observations (e.g., notepads or word processors). Perhaps for reasons of cost, connected to the time and energy involved, participant observation is a style of research that is most frequently engaged in by scholars at the early stages of their academic careers.

Disadvantages

Just as significant advantages characterize this methodology, several disadvantages are evident. Among the key problems that have been described are those relating to proof, generalizability, bias, and time commitments.

Proof

Participant observation relies upon a single case study: the examination of one place, one scene, and one group. This raises questions about the nature of proof, or, put another way, about reliability. Will two researchers examining similar social scenes reach the same conclusions? Often because of different perspectives upon entering the field and different experiences while observing, conclusions vary greatly. While the observations and the interpretations of those observations may be compelling, a reader can reasonably wonder whether any set of conclusions is definitive.

Generalizability

Even if we accept the legitimacy of analyzing one scene, on what grounds can we generalize beyond that setting? How far can our conclusions be pushed? Participant observation research has a problem in this regard because of the absence of scientific control that characterizes experimental research and produces confidence in the claim that important variables of social life have been adequately captured. As a result, the extent to which generalizability is legitimate will inevitably be problematic in participant observation research. Participant observers must present a theoretical model that helps readers judge the legitimacy of their broader claims in light of the audience's own experiences. Do the findings apply only to one setting at one moment, or can they be extended?

Bias

A strength of participant observation methodology is that the researcher's insight and perspective are taken into account, but this strength has a downside. It is difficult to distinguish between perspective and bias – the former with a positive implication, and the latter with a negative tone. The personal background and set of experiences that the researcher brings to a scene will inevitably be distinctively different from those of other researchers and, for that matter, from the perspectives of the participants in the setting. To the extent that the researcher's perspectives differ significantly from those of the participants – possibly because of the generally progressive values and upper-middle-class status of academics – the understanding of a particular scene may be systematically biased.

Time

Just as participant observation research is relatively inexpensive, it is also highly labor intensive. This style of research requires that the researcher be present in the observed social scene. One cannot visit quickly, but must spend extended periods of time so that the full range of activities in which participants engage is seen and understood. Much participant observation depends upon the vagaries of chance – what happens to occur at the moment of observation, and, as a result, a significant investment of time is needed. While there is no definitive rule for the appropriate length of time necessary for observation, most projects require months, if not years, to complete. Coupled with a modest requirement for capital equipment, this means that, as noted, this methodology is feasible for younger scholars. As a result, participant observation studies often do not have the depth of theoretical understanding that is more likely to characterize the work of senior scholars.

The Growth and Development of Participant Observation

Although participant observation methodology has deep roots in ethnographic traditions (including in travelers' accounts and missionary tales), participant observation within the academy has its origins in the discipline of sociology at the turn of the twentieth century, particularly with scholars affiliated with the Department of Sociology at the University of Chicago. Notable at this early stage were the participant observation studies of Annie Marion MacLean, a student at Chicago and later a professor at Adelphi University. Maclean worked and observed in department stores, sweatshops, and coal fields in order to gain an appreciation of conditions in these scenes. By the 1920s, participant observation was well established at the University of Chicago, as evidenced in studies by Frances Donovan on the lives of waitresses and Frederic Thrasher's observations of gang life. Although members of the 'Chicago school' of sociology employed numerous methodological techniques, these scholars were probably best known for their observational research and depiction of the life stories of informants. By midcentury, participant observation had expanded well beyond the bounds of Chicago. Classic works such as Whyte's (1943) *Street Corner Society*, Hollingshead's (1949) *Elmtown's Youth*, Vidich and Bensman's (1958) *Small Town in Mass Society*, and Gans's (1963) *The Urban Villagers* collectively demonstrated that through intense involvement in a community, a researcher could gain a perspective on a social domain that was both empirically and theoretically powerful. The fact that many of these research projects covered life in city environments eventually led some to describe this approach as 'urban ethnography,' an approach that has become more prominent in the past 20 years, as exemplified in Anderson's (1992) *Streetwise*, Duneier's (1999) *Sidewalk*, and Pattillo's

(1999) *Black Picket Fences*. Another stream of participant observation research was grounded in the study of deviant groups and activities. Researchers in such domains have the dilemma of determining the degree to which participation should bolster observation, a problem that is simultaneously strategic, ethical, and legal. Exemplifying such research are studies of the mentally ill, gang members, and drug dealers, notably the influential works by Goffman (1961) *Asylums*, Liebow (1967) *Talley's Corner*, Horowitz's (1983) *Honor and the American Dream*, Snow and Anderson's (1993) *Down on Their Luck*, and Venkatesh's (2008) *Gang Leader for a Day*. These themes – gritty urban life and troubling social deviance (and their control) – have been integral to participant observation. The increased interest in these themes over the past few decades has created a 'new urban ethnography' that focuses on broader issues of urban poverty and racial injustice, along with the analysis of group dynamics and local cultures.

Not all researchers focus on social problems. In the last few decades, beginning with the inspiration of the Hawthorne studies, and continuing the research of Donald Roy, Melville Dalton, and Robert Jackall, increasing attention has been paid to observations of workplaces. The participant observation of organizational life has developed rapidly, creating an active focus on the dynamics of organizational domains, both in traditional social science departments and within schools of management. Factories, airlines, restaurants, and high-tech engineering firms have all been the foci of research. Yet, every social world in which individuals with a common interest meet and to which they hold affiliation can be analyzed through participant observation, whether clubs, sports teams, or bars.

Comparison with Other Field Methods

It is easy to assert that participant observation is synonymous with qualitative field research, and, in reality, the lines are blurred. There are now so many different, overlapping approaches, which have been given different names, even if the styles and traditions of research do not differ much. However, participant observation can be contrasted with several other techniques with which it shares some commonalities. Some scholars engage in 'ethnographic immersion.' In such investigations, the researcher becomes a full member of the group and, in effect, studies his or her own group. In this case, it is claimed that the researcher has 'gone native.' This strategy has the advantage that the researcher comes by his or her 'member's knowledge' naturally, but simultaneously the immersion may diminish the ability to examine the group life from the critical, outsider perspective that being marginal sometimes brings. Most forms of participant observation involve a distinction between being a researcher and being a full member of the group studied. Typically, members are told that they are being observed by an outsider, who, for purposes of the study, may participate actively in the life of the group, even though she or he is not a full member and is not recognized as such.

A second technique, related to ethnographic immersion, has been labeled 'auto-ethnography,' akin to the methodology of introspectionism of the early years of the twentieth century. In these studies, the researcher mines his or her life experiences and emotions, hoping to demonstrate the embodied characteristics of social forces. One such example is Ellis's (1995) *Final Negotiations*, an emotional and analytical account of her own reaction to the lengthy dying of her significant other. This writing, while occasionally powerful, insightful, and moving, can be faulted for its reliance on subjective experience. Auto-ethnography might be seen as an extreme instance of total immersion, with nothing outside the researcher's experience; given this personal source of data, these provocative arguments become difficult for others to evaluate. The author proposes a singular account of emotions that, because it is his or her account, leaves no room for alternative interpretations.

A third approach is to collect data by means of in-depth interviews. Most participant observation involves extended questioning of informants. However, some research relies on this questioning to the exclusion of direct observation. This method has the advantage of permitting the researcher to gain multiple perspectives of the same scene and permits the investigation of domains to which it might be impossible to gain direct access. However, in-depth interviews also limit the researcher to the presentations of interested parties. The claims that are revealed in interviews may be systematically different from the private thoughts of informants and may also differ substantially from their behavior. Observations provide a check on what one is told for reasons of impression management. As always, triangulation of data provides advantages, curbing the weakness of any one methodology.

Fourth, some researchers deemphasize participation and are, in practice, pure observers. One group of observers makes precise statistical measurements of public behaviors, but this approach is distant from participant observation. More relevant are those scholars who examine public behavior, particularly behavior within open urban spaces. This distinguished tradition of scholarship includes such researchers as William H. Whyte, Erving Goffman, Lyn Lofland, and, more recently, Carol Brooks Gardner. A close reading of street activity, parallel to certain forms of animal ethology, permits the recognition of patterns of human activity.

Within participant observation itself, researchers select particular roles or strategies. The key dimension on which roles can be differentiated is the extent to which researchers choose to be involved in group life. Adler and Adler (1987) distinguish participant observation methods according to the extent of active involvement: peripheral membership, active membership, and complete membership. In general, the peripheral member observes as an outsider to the group and its culture, whereas the active member is directly engaged in the life of the group, while making it clear to the group that she or he is not fully a member and is conducting research. In the model of the Adlers, the complete observer engages in ethnographic immersion, sometimes informing the group of the research goals.

Strategies of Participation Observation

Unlike many techniques of quantitative research and statistical analysis, there are no firm and fast rules that determine how participant observation research should be conducted. Such a reality has proven frustrating to generations of students who desire definite directions. Traditionally, a novice learned the

skills of participant observation through what amounted to an apprenticeship relation with a senior researcher. However, because of the increasing numbers of field researchers, many social science departments, particularly those in sociology and anthropology, have instituted field methods courses in which some rudimentary – and flexible – strategies of the method are taught.

Access

The first issue that must be confronted in a research project is the question of access. How does one convince a group that they should willingly open their activities to a stranger whom they do not know and whom may criticize the group? This is especially applicable to groups that are generally perceived as deviant (criminal gangs or politically marginal movements), but it also recognizes that any group, striving to maintain boundaries that differentiate it from others, may engage in some activities that members wish to shield from outsiders and that could be viewed negatively. Participant observers must, within the limits of their ethical standards, persuade the group that they can be trusted not to violate shared expectations. Through this process, they set the rules of engagement. Such rules, explicit or implicit, are uniquely formulated for each project. Further, this access emerges and changes over time. One is rarely accepted all at once, but often the group maintains a cautious vigilance until they become satisfied that the researcher can be trusted. The researcher is continually being tested. The participant observer must be sensitive to this process of judgment.

Socialization

Access is only a first step. Once the researcher gains entree to a setting, he or she must determine what 'behavior' means. In effect, the participant observer must become socialized to the environment with its norms, cultural traditions, and jargon. The ease of this process varies as a consequence of how well acquainted the researcher is with the setting prior to the observation, but unless the researcher begins as a full member, a process of acculturation will typically have to be mastered. At times, the group will become frustrated by the lack of competence of the observer, but more often this process of learning is valuable as a methodological strategy, permitting the researcher to ask questions that would be denied to full members as being too obvious.

Developing Relationships

Participant observation is a methodology that depends upon the establishment of relationships. It relies upon sociability. One essential skill is the ability to recruit informants from the field. The most important of these are termed 'key informants,' such as Doc in Whyte's (1943) classic *Street Corner Society*. These individuals serve both as guides for the participant observer and as a means of vouching for the researcher's legitimacy within the setting, providing an insider's stamp of approval. The researcher who lacks the ability to make connections will have difficulty collecting credible research data.

Field Notes

The researcher not only needs to observe activity, but also must subsequently inscribe that material in what are labeled 'field notes,' documents that serve as the evidentiary basis of the published report. Considerable discussion has addressed what constitutes appropriate field notes and how these notes should be presented (Van Maanen, 2011). These notes provide the 'facts' that are observed, including actions, statements, and the feelings of the observer. Participant observers are enjoined to write as much of what transpires as possible, particularly in the early stages of the research when one is determining what issues are most salient. This emphasizes that participant observation is often an inductive methodology, with the field data intuitively revealing the important issues, rather than deductively testing preestablished hypotheses.

Exit Strategies

Much research simply ends. Once completed, the project closes down. Exiting is rarely as simple as this in participant observation because the researcher and informants have developed intense social ties. Leaving the field involves the termination of a set of powerful relationships, and sometimes produces loneliness or even betrayal among either party. As a result, the process of disengagement often involves a longer period, and some connection with the field setting often continues, even if the research is officially completed. Researchers are often advised – for both practical and ethical reasons – to share their writing with their informants, either to gain additional feedback or to permit those informants to use the analysis for their own ends. The linkages that are established during the course of the observation can be a continuing source of strength, both for researchers and for informants.

Ethical Concerns

Although all forms of research that involve human subjects raise ethical issues, the variety of ethical concerns in participant observation is particularly great because of the degree of interpersonal dynamics involved. Four ethical issues have been central to participant observation research: deception, informed consent, confidentiality, and the accuracy of depiction. Although these by no means exhaust potential ethical concerns, each one raises important issues.

Deception

Most participant observers agree that it is both pragmatically and ethically necessary to announce to one's informants that one is conducting research. In part, this is because participant observation depends on personal relations among individuals, who, for the period of time of the study, are status peers. To claim to be something that one is not – to pretend to be a full member of the group – without revealing one's purpose could undermine the entire enterprise if it becomes discovered. Lies are often difficult to maintain for long periods. Further, deception suggests that one's interests take priority over the interests of another: can we justify such trickery? While research on groups that hope to keep their activities hidden from

a wider public – either deviant groups or, occasionally, elite groups – motivates deceptive practices, such strategies are troublesome.

Informed Consent

Deception involves the active misleading of others, but how should we view the absence of full disclosure? Do group members have the right to know that they are being investigated? For instance, one can easily join a leisure group without announcing that one is taking notes or planning to publish. Is this morally proper? As noted, good reasons may exist for announcing one's presence, permitting one's informants to serve, in effect, as research assistants. But should researchers be required to gain the informed consent of their informants; further, how much information is necessary for informed consent, particularly in a methodology that depends on inductive methods in which the researcher may truly not be aware of what issues will eventually become central to the analysis? One's topics depend on what one observes. During the past few decades, American universities have instituted *ethics* committees (Human Subjects Committees and Institutional Review Boards) that are designed to protect the rights of research subjects. Frequently, researchers are required to gain some measure of informed consent, but how much information is required remains a matter of debate.

Confidentiality

One element that most (although not all) researchers agree on is that informants' names and clearly identifying information should not be included in any published research report, although some who critically examine elites feel that such forms of anonymity are not essential. In general, researchers believe that publishing the names or identifiers of particular informants or settings is neither necessary nor warranted. At times this decision poses a problem in that field notes may describe actions or statements that can be recognized, certainly by others within the scene. As a result, participant observers must choose how much information to alter to preserve confidentiality, even when this shades the full 'facts' of the case.

Precision of Description

Although it is clearly desirable to present data that are precisely accurate – direct quotations and exact descriptions of behavior – participant observation methodology and the limits of human ability make these values unattainable goals, as argued in my *'Ten Lies of Ethnography'* (Fine, 1993). In part we are imperfect in our ability to depict reality, but in part we may recognize that the details of human activity may actually obscure our crucial analytical points. For instance, the speech of informants, like the speech of researchers themselves, is marked by false starts, errors, and grammatical infelicities. Further, so much behavior is happening at any given moment that the researcher can easily become overwhelmed with a surfeit of trivial observations. The ethical balance that must be struck is to do justice to the events that are transpiring, while simultaneously making the account as clear as possible to permit communication with readers.

Summary

This brief overview examines central features of the participant observation methodology. In doing so, I have deemphasized both the strategies of analysis (the extended case study method and grounded theory) used by practitioners and the modes of presentation (realist tales and impressionist tales). No method of data collection can exist without related techniques by which data are analyzed and presented.

Throughout the history of modern social science, participant observation has proven to be a powerful technique by which researchers can understand a diverse set of social worlds in a way that does justice to the complexity of the activities of group members and to their own perspectives and understandings. While this style of research benefits by the triangulation with methodologies in order to create adequate theoretical understanding, participant observation provides the basis by which researchers can understand the richness of the social settings that they – and others – inhabit.

Abstract

Often used in attempts to merge theory with practice and to collaboratively generate solutions to practical problems, participatory and action research have emerged as leading approaches within the social and behavioral sciences. While there is no one definitive form of action or participatory research, this article focuses on participatory action research (PAR) and highlights its key features and functions, drawing on examples of its application. An overview of some of the studies and settings within which PAR has been frequently used is presented. The article concludes by reviewing significant challenges and opportunities for researchers employing these participatory and action research methods within the social and behavioral sciences.

Introduction: What is Participatory and Action Research?

'Participation,' 'research,' and 'action' are often perceived as the bedrock for action research methods and the merits of these approaches to research have been identified as their ability to generate both rigorous scientific evidence and solutions to practical and policy problems. Moreover, their potential to empower communities and practitioners has been recognized. In the past, participatory and action orientated approaches were concerned primarily with collecting and sharing the views of interested people as an end in itself. Increasingly, the democratic and collective nature of knowledge creation is generating more intensive study and interest. While participatory and action research approaches are not new, developments in the employment of these approaches have resulted in a more critical participatory action research (PAR) agenda, which has garnered a recent revival in interest, earning it a spot as one of the leading approaches within the social and behavioral sciences. The following sections briefly review the origins of participatory and action research before examining the form and features of PAR.

Participatory Approaches

While there are numerous participatory approaches, for the purposes of this article it is important to distinguish participatory research as a research method in contrast to research surrounding participatory planning and decision making.

Participatory approaches in planning in particular gained prominence in the 1970s and the early 1980s. Interest in these approaches has grown as researchers began to realize that the opinions and priorities of individuals should be incorporated into policy development and project implementation, paralleling a shift from top-down, autocratic interventions toward a new emphasis on bottom-up, democratic empowerment. Since the 1990s the latter view is dominant, and indeed increasingly expected, among policy makers. The often-stated policy goal of involving all stakeholders, especially those who previously did not have a voice, reflects this emphasis on bottom-up approaches in which the participants in the research are involved in decision making and the selection of priorities. Within planning and policy-making arenas, there are frequent debates not only about the type of the engagement that is required by participating groups but also in the extent to which that engagement is linked to decision-making practices. Arnstein's (1969) classic 'ladder of citizen participation' is often employed to categorize varying degrees of participation, from low, limited, or nonparticipation, through tokenism (consultation, information provision, and placation), to high levels of participation (involving *participants as coresearchers* and forms of citizen control). Early participatory approaches were often critiqued for centering on the lower end of Arnstein's ladder of participation, focusing, for example, on limited consultation through opinion poll surveys and/or public meetings. The growth in participatory approaches has resulted in a plethora of new tools and techniques, including citizens' juries, visioning, world cafes, consensus conferencing, appreciative inquiries, forum theaters, and planning for real.

While participatory research is frequently utilized by researchers concerned with planning and policy making, participatory research is distinct from participatory planning. It is essentially a method where the central aim is to develop a process where locally based knowledge emerges to develop theory that is sensitive to local contexts. Participatory research involves conducting research *in conjunction with the people whose lives and activities are under investigation*. Moreover, priority is given to the views and attitudes of local people, recognizing them as *the* experts within *their own* environments. Participatory research approaches have a long history and are frequently associated with social transformation in the developing world. Often viewed as an alternative philosophy of social research, participatory research has its origins in liberation theology and neo-Marxist approaches to community development, for example in Latin American contexts (Freire, 1972). But it also has roots in human rights activism, for example in Asia (Kemmis and McTaggart, 2008).

Participatory research strives to be inclusive (involve all, or representatives of all, groups who will be affected by the outcomes of a process regardless of their status); transparent (with open dialogue and communication); and empowering (should promote mutual learning and empowerment). Cooperation and sharing of responsibility of power are seen as essential elements within participatory research. However, there are varying degrees of participation and engagement that can be evident in any participatory research project. Cornwall

and Jewkes (1995) contend that researchers primarily use four modes of participation within participatory research. The first and weakest form is *contractual*, a process whereby people essentially act as informants in a research study; they are contracted onto the project of researchers. The second, *consultative*, is a form of participation where people are asked for their opinions and consulted by researchers prior to actions being taken. The third form, *collaborative*, involves researchers and local people working jointly on projects formulated, designed, and coordinated by researchers. The final form is termed *collegiate* where researchers and local people work collectively as colleagues, combining their different skills in the cocreation of knowledge and learning. While in theory the goal of many participatory researchers is to adopt this *collegiate* form of participation, in practice very few researchers implement this form throughout the entire research process.

Overall, participatory research offers opportunities to critically explore 'how' data are gathered, 'what sort' of new information and knowledge is gained, and 'what impacts' it has on a community. Three particular attributes of participatory research which often serve to distinguish it from conventional research are community-based analysis of social problems, shared ownership of research projects, and an orientation toward community action (Kemmis and McTaggart, 2008).

Action Research

Action research involves relevant parties engaging in current action with the objective of altering and improving it. In this way this research approach is similar to the commonsensical concept of 'learning by doing.' Action research is not just research which we anticipate will be followed by action; i.e., changes to behavior do not just happen at the end of the research, they can occur throughout the process as the research develops and as participants contemplate and progress their understandings about their behavior. Social psychologist Kurt Lewin is credited with devising the term 'action research' in the 1940s. Drawing on his work with community action programs in the US at that time, Lewin (1946) coined the term to describe the cycles of reflection, action, and problem solving in research.

A review of the literature points toward three vital elements of action research: its participatory character; its democratic impulse; and its contribution to both social science and social change (Meyer, 2000). With regard to participation, an essential element is that participants must be willing to play an active role in the research process. Here it is action that is important, as while the majority of research requires willing participants, the level of commitment required for action research often requires far more than agreeing to answer questions in a survey or to simply be observed. In action research, participants can play an important role in shaping the research process. For example in many action research projects the researcher together with the participants highlight actions to take and collectively they analyze results, critically consider the actions taken and results obtained, and formulate new courses of action. Consequently, this approach is often deemed more democratic than other methods because often the researcher and participants act jointly to realize results for change. In addition to ongoing consultation with participants throughout the research process, a critical feature within many action research projects is that findings can be fed back to the participants during the research as well as at its conclusion. Subsequently, it has been argued that the outcomes of the research are more closely grounded in the reality of day-to-day practice than other methods and have been deemed to be more meaningful to practitioners. Finally, it has been suggested that through action research "academics can learn from what takes place on the ground in order to investigate their own theoretical endeavours and overcome some of the distance between theory and practice" (Halfacree, 1999, p. 209) to generate solutions to practical problems while maintaining attention to broader conceptual practices (Kitchen and Tate, 2000).

Views of action research are constantly changing and developing. While there are many differences between action research and participatory research, researchers are increasingly focusing on their points of convergence. As a result the past two decades have seen the emergence of a plethora of hybrid approaches, including cooperative inquiry, participatory learning and action, emancipatory action research, community-based participatory research, and participatory learning research (Kemmis and McTaggart, 2008; Kindon et al., 2007). Changing a problematic situation for the better by using the insights into everyday activities as voiced directly by the people concerned is a common aim of all these approaches.

Drawing on the strengths of both action research and participatory research approaches, PAR is another approach specifically employed to enhance collaboration, empower participants, and advance knowledge acquisition and social change. As it has an extensive history in many fields of social and behavioral sciences, including social-scientific and interdisciplinary sustainability research, the remainder of this article will focus on PAR.

Guiding Principles and Key Features of PAR

Although definitions vary, most commentators agree that PAR involves practical problem solving in real-life situations where researchers work with, and for, people, as opposed to undertaking research about them. Essentially PAR is guided by four key principles: collaboration through participation; empowerment of participants; garnering of knowledge; and initiation of social change.

PAR is committed to ensuring that the research will benefit the community and contribute to the well-being of the participants, rather than considering them as simply objects of investigation. PAR involves 'research with' as opposed to 'research on' participants/communities providing practical investigation of real people in real contexts, which results in real and concrete applications. A core objective of PAR is to improve the circumstances and well-being of the participants through the research process. PAR is a learning process that strives to take account not only of the actions of people but also the interactions of people among themselves and with the world about them. This research approach explores the history of the people under investigation, in addition to embracing their everyday lifestyles, behaviors, and practices set in their social and cultural context. Power sharing is another central concept underpinning PAR. By reflecting on the information gathered and by understanding the social context and

interaction of the people under investigation, PAR aims to empower people to take control of their futures and to enhance them for the better.

Thus, PAR is committed to the 'opening up' and demystification of research and the destabilization of hierarchical relationships between researchers and participants. It also can help to create a perception of field research as a learning process and an educational tool.

PAR Methods and Outputs

As should be evident from this article thus far, PAR is not simply about data collection. While there is no one single methodology that typifies a PAR approach, a general guideline for methods employed within PAR is the adoption of a structure which adheres to a cyclical process of action and reflection. When designing a PAR project, considerable time is dedicated to planning the process in a constructive collaborative manner among all participants. This initial phase aims to identify the issue in need of change and recognizing the strengths and assets of all the participants. This is then followed by an action stage: utilizing the capability and assets within the group to instigate change and improvement of a situation. The changes outlined in the initial plan are observed on the ground and recorded. All research participants reflect on and evaluate the action process.

PAR methods should be context specific and developed collaboratively between researchers and participants. Consequently a PAR project may employ a range of qualitative and quantitative methods to suit specific objectives. Methods frequently used in PAR can include traditional and innovative approaches such as interviews, surveys, video and photography, mapping (paper maps as well as outputs from GIS), oral narratives and storytelling, participant observation recordings, diaries or journal entries, field-trip excursions, focus groups, and collaborative data analysis.

As it involves a holistic approach to problem solving, research tools and techniques may be combined in innovative ways as a PAR project progresses. Outputs from PAR often represent a diverse range of both traditional and innovative outputs (e.g., results are often disseminated through public workshops and social media platforms in addition to traditional academic journal articles and formal presentations). The coproduction of outputs, such as presentations, video clips, and written reports, is increasingly common within this research approach.

As a primary goal of any PAR process is social change, the importance of producing action-orientated outputs cannot be overstated. Nevertheless, the actual impact of the outputs is equally critical to the success or failure of a PAR process. In fact, PAR could serve to reproduce and even exacerbate existing inequalities unless it actually translates stated goals into tangible actions that contribute to the improvement of participants' lives (Kindon et al., 2007).

PAR Applications

Although used extensively for the past two decades in the field of health sciences, social work, and education, PAR is only emerging as a prominent feature in other fields such as human and social geography, (environmental) sociology, or environmental studies. Within these disciplines participatory research approaches were originally employed primarily to 'give voice' to previously marginalized participants, rather than to generate change in behavior either of the participants or in policy circles (Hoggart et al., 2002). The growth of PAR (with an emphasis on action) in these research fields is evident in research conducted by the Global Action Plan *Eco-teams* project, which was designed with the primary objective of changing household actions with regard to a number of behaviors including energy and water conservation (for more information see www.globalactionplan.org.uk). Similarly, in the field of waste management Fahy and Davies (2007) worked with householders to develop practical ways in which they could change their waste management practices while, at the same time, garnering information from them about the feasibility of such practices for their particular lifestyles.

This research approach was utilized by Mark Garavan (2013) in a project which reveals his experiences in the early- to mid-2000s researching and representing a local community in County Mayo in the west of Ireland whose members have resisted the construction of a large-scale gas pipeline project. His research highlights that local responses to the pipeline development involve culture-specific cognitive and linguistic efforts as well as visceral reactions by people who feel that the future of their place, community, and livelihoods is under threat. This shows how local people's concepts of sustainability are often very different from rational-scientific discourses that dominate most sustainability debates. Throughout the research Garavan argues for a participatory approach to research that takes the concerns and voices of the participants seriously and adopts a long-term view of human life and the research process. There are other numerous calls for the application of PAR to pressing sustainability challenges such as climate change and biodiversity loss (see Reason, 2007).

Considering current and future trends for PAR, technological innovations such as smart phones and other personal technological devices as well as the explosion of social media platforms are opening up new forms of knowledge creation. These innovations have the potential to empower and facilitate people to more actively engage with research activities. This increasing coproduction of knowledge is particularly evident in a number of recent geographical information systems-mapping projects which amalgamate data gathered by individual citizens of their local environments (see for example the Open Street Maps project (Huckley, 2010). Also see Howe (2009) for an overview of crowdsourcing and Goodchild and Glennon (2010) for crowdsourcing applications in the field of disaster responses.

Critiques of PAR

While PAR has the potential to give marginalized groups the ability to generate knowledge and power through research activities, there are also critical voices who view as exaggerated assumptions surrounding the use of the research process as an empowerment tool (Cooke and Kothari, 2001). Indeed, the approach has the potential to reproduce existing inequalities i.e., replicate preexisting power relations within a participating

community. Many projects employing the PAR approach attempt to dispense with traditional roles and titles of researcher and participant. However, this can result in confusion over the role of those assisting others on how to conduct PAR. The illusion of occupying a neutral role while remaining in control of the research project, for example making the decision to cast specific communities or participants as subjects requiring research, is clearly problematic.

Furthermore, detractors of PAR see the potential for new hierarchies to emerge. For example, certain local knowledge could be prioritized simply because of the participatory process that produced it. Similarly if researchers become established as experts in PAR, or indeed if they classify other methods – that are not participatory – as less valid, PAR researchers could be accused of replicating the very hierarchies they aim to challenge. As with any research approach, it is important to adopt a self-reflexive position, acknowledging the limitations of PAR and recognizing that although power is inherent within it and the research process can shape people's behavior, it does so with the aim of providing them with the means to challenge and change more dominant power structures and relations in their lives (see Kindon et al., 2007 for a full discussion on the negative power effects of PAR).

In addition to broader concerns over the use of their techniques and terms and the dangers of becoming co-opted into top-down policy and research initiatives, participatory action researchers face a number of practical challenges when undertaking research.

Challenges and Opportunities Involved in Undertaking Participatory Action Research

As with all research approaches, PAR has a series of practical limitations, including demands on researchers' and participants' time, issues of trust, (lack of) coordination of different skills and levels of participation, and attempts to meet a number of divergent goals (for an in-depth discussion see Breitbard, 2010). PAR approaches can be extremely resource intensive when compared with many other research approaches. In addition to the potential direct costs associated with many intervention and action studies, a PAR approach requires more time and effort on behalf of both researcher and participant than research methods such as one-off interviews or focus group discussions. This research approach is demanding of participants and if individuals are not interested in participating then this may affect the kinds of people willing to do the research and therefore skew results. There are differing degrees of 'action' in PAR and there is a need for balance between how much 'action' you can require of participants and whether they will be willing to participate.

Another possible limitation is the problem of extension. Frequently PAR is conducted on a small scale incorporating case studies. Scaling up these studies may thus prove to be impractical. For example, when Fahy and Davies (2007) utilized household waste minimization exercises to explore waste management behavioral change in Ireland, almost all of the participants in the sample of 10 households recommended that regular home visits were one of the most successful ways of raising awareness about waste and improving waste management behavior. However, conducting such an exercise on a larger scale would require significant investment of time and effort that is impossible without adequate financial support.

Reiterating the importance of action-orientated outputs and the significant role of power processes within PAR, uncertainty surrounding the potential transformative power of the research presents an inherent challenge. Cooke and Kothari in their book *Participation: The New Tyranny* (2001) posit that the theoretical ideal of participation often does not live up to its rhetoric as an instrument for social transformation and a redivision of power. In this book they contend that many initiatives embracing participation result in the maintenance of existing power relationships, i.e., this power is disguised behind the methods and rhetoric of participation.

While social change may be one of the goals of a specific project, it may be impossible from the outset to gauge the impact of the research produced. Even when policy makers and regulators are active coresearchers alongside publics and academics, key decision makers are rarely formally obliged to adhere to any of the recommendations resulting from the research. For example Fahy and O'Cinneide's (2009) research on community mapping in Galway City in the west of Ireland was instigated through a PAR project funded by a national-level agency and mediated by research staff of a local university, with community groups throughout the city actively collaborating with the municipal authority. The research process in addition to generating high levels of public participation and opening up spaces for shared reflections on local areas, resulted in the creation of a map providing grassroots perspectives of the city. It details aspects of life that various publics have identified as important to them. However, even though the municipal authority were central to this project and actively engaged in dialogue with citizens and communities about their local environments, there was no obligation on the council to utilize the data collected in future city planning.

Despite these potential limitations, PAR offers researchers a very rewarding and exciting approach to researching pressing social and environmental sustainability issues. In addition to providing nuanced understandings of lived contexts and everyday actions, the data produced have the potential to initiate actions that address people's real needs and desires.

Conclusion

To conclude, PAR potentially offers a range of opportunities for those involved in social and behavioral research, not least by enhancing learning opportunities for all participants. Overall, this style of research involves more engagement between researcher and participant relative to other methods of research, such as questionnaire surveys. It is not simply another form of consultation; instead projects based on PAR aim to be exemplars of active coresearch, *for* and *by* the researched. This contrasts with more traditional research methods that clearly differentiate between researcher and researched and that place the generation of 'objective' scientific knowledge over and above the (research) needs of those being studied. In addition, PAR can offer a more nuanced understanding of information gathered from other methodological sources. Within the social

and behavioral sciences, investigating understandings of the contextual variables which influence behavior is critical and PAR approaches can assist in providing such understandings.

Abstract

Participatory approaches to doing research have gained critical attention from across the behavioral and social sciences, as scholars, activists, and practitioners committed to social change work closely with communities to investigate their concerns, develop proposals for transformative change, and identify new questions to investigate. Rooted in principles of justice and democracy, participatory action research (PAR) is an inclusive, collaborative approach to research defined both by participation and a determination to produce knowledge in the interest of social change. Within the social sciences, PAR is a stance committed to engaging knowledge and expertise beyond the 'ivory tower' by involving those who are most intimately affected by the research in shaping the research questions, framing interpretations, and designing meaningful research products and actions.

> The silenced are not just incidental to the curiosity of the researcher but are the masters of inquiry into the underlying causes of the events in their world. In this context research becomes a means of moving them beyond silence into a quest to proclaim the world.
>
> Paulo Freire, 1982: 30–31

Definition

Rooted in principles of justice and democracy, participatory action research (PAR) is an inclusive, collaborative approach to research defined both by participation and a determination to produce knowledge in the interest of social change. Within the social sciences, PAR is a stance committed to engaging knowledge and expertise beyond the 'ivory tower' by involving those who are most intimately affected by the research in shaping the research questions, framing interpretations, and designing meaningful research products and actions. Marked by an inclusive orientation, PAR expands traditional notions of expertise, repositioning those who have been traditionally 'researched' and excluded from the academy (historically oppressed groups including people of color, young people, people with disabilities, LBGTQ, undocumented, incarcerated, poor, working class) as research partners. More than simply a method, PAR is an epistemological position grounded in everyday life experience and a commitment to the 'right to research' (Appadurai, 2006). In this way PAR reflects a critical challenge to positivist epistemology and academic research traditions that assume knowledge to be produced by credentialed experts who are qualified to measure and analyze an objective reality. In contrast, PAR is founded upon a belief that all knowledge is collectively produced. Decentering individualized expertise, PAR draws from situated knowledge and assumes that the subjects and agents of knowledge are multiple, heterogeneous, contradictory, embodied, and socially constructed.

Participatory approaches to doing research have gained critical attention from across the behavioral and social sciences, as scholars, activists, and practitioners committed to social change work closely with communities to investigate their concerns, develop proposals for transformative change, and identify new questions to investigate (Kindon et al., 2007). At the same time critical scholars have pointed to the ways that broad applications of the term 'participation' may mask tokenism and provide an illusion of consultation (Cooke and Kothari, 2001; Arnstein, 1969) when participatory research is presented as a set of techniques rather than a commitment to working *with* communities, as this may result in the reproduction, rather than the challenging, of social inequities.

The important debates and questions within the field of PAR revolve around the intertwined relationship of knowledge and power. More recently, there have been moves to reassert the critical underpinnings of PAR and highlighting its liberatory history and connection to feminist, queer, critical race, neo-Marxist, and indigenous theories (Torre et al., 2012). Critical participatory action research (CPAR) centers this analysis, joining social movements as a transformative social justice project committed to documenting the grossly uneven structural distributions of opportunities, troubling ideological categories projected onto communities, demonstrating how science has been recruited to legitimate dominant policies and practices. To this end, CPAR has profound implications for rethinking the politics of representation and challenging what Foucault (1980) identified as the 'subjectifying social sciences.' Taking seriously the intertwining of 'the global and the intimate' (Pratt and Rosner, 2006), CPAR reflects a commitment to map out the relationships between social structures and injustice in everyday life experiences. Critical PAR considers how questions of political economy, geopolitical context, and identity (race, class, gender, sexual orientation, and status) are made meaningful in a particular context and raise up questions of vulnerability and power.

Epistemological and Ontological Orientation of PAR

Drawing upon situated knowledge and life experiences, the epistemology and ontology of PAR challenge traditional approaches to research through its emphasis on collaboration and the integration of theory and practice. In this way, a participatory approach takes seriously what it means to do

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10554-9

social science (c kinpaisby-hill, 2011). By working collectively with coresearchers in participatory ways, PAR shifts the often hierarchical social relations within research that produce knowledge in isolation from the very communities who are most affected by the research. Recognizing that all knowledge is socially produced, a participatory epistemology is based on an ontology that affirms the capacity of human beings for creative thinking, analysis, and creativity. Recognizing the connectedness of knowing, doing, and being, participatory praxis destabilizes dualisms between theory and practice offering 'an alternative ontology of theorizing' that moves between social constructions and embodied and emotional experiences (ibid). As c kinpaisby-hill explains (2011: 223), PAR "is a citational process, a relational bricolage of one's own and other's ideas, and it is an embedded and constantly ongoing praxis of coming to knowing through iterative cycles, moving between experiences of everyday social life and individual and collective analysis and reflection."

Historical Roots

Building upon the long-standing traditions of grassroots social movements, critical pedagogy and activism, and legacies of critical race, decolonizing, and feminist theories (Smith, 1999; Kelley, 1997; hooks, 1990; Torre, 2009; Freire, 1970; Fals Borda and Rahman, 1991), PAR's historical roots traces different interdisciplinary lineages from around the world, from liberation theology, to critical psychology, sociology, and geography (Martin-Baro, 1994; Lewin, 1946; Wormser and Selltiz, 1951; Du Bois, 1898; Bunge, 1971).

Within the United States, the theory and methods of action-oriented research in the social sciences is often attributed to the work of the social psychologist Kurt Lewin. His seminal article, "Action research and minority problems" published in 1946 insisted that 'minority problems' were indeed 'majority problems' and that social science conducted through collective research should be aimed at changing communities and social institutions. Lewin's description of action research involved a spiral of self-reflective cycles of fact-finding, action, observation, evaluation, and then replanning and more fact-finding, action, and evaluation. Convinced of the important role of social science in informing social change, Lewin established Commission on Community Interrelations, an early university partnership with an advocacy organization, dedicated to developing research and methodologies wherein community groups joined researchers as 'fact-finders' to study 'real-life' situations and produce knowledge that would affect social change. One such method, formalized through the leadership of Margot Wormser and Claire Seltiz, was the Community Self-Survey that brought together diverse teams of community members and researchers to engage in large-scale participatory research on discriminatory practices in housing, employment, education, and public services in their communities (see Torre and Fine, 2011). These surveys echoed the early sociological work of Jane Addams and the residents of Hull House in Chicago and W.E.B. Du Bois in Philadelphia and Atlanta that took place in the 1890s. Addams and Du Bois rejected contemporary frames centered on the 'immigrant' or 'Negro problem' and positioned individuals and groups as pathological or problematic. Instead they each argued for structural analyses of race- and class-based oppression, asking what are the policies, institutions, and social arrangements that enrich and limit human development? With this new framing, the 'problem' became one of classed and racialized patterns of housing, sanitation, education, criminal justice, and access to health care and healthy environments.

Other roots of PAR that have nourished present practices of PAR lie within liberatory popular education movements, particularly those in the southern United States and Latin America. Working with communities in the Appalachian Mountains, Miles Horton, a co-founder of the Highlander Research and Education Center used participatory education and research to organize communities around worker and civil rights beginning in the 1930s. With inspiration from the Hull House, Horton's work emphasized community participation, arguing that effective institutional change would come about only with solutions determined by people who were directly experiencing the problem and who would be most affected by any actions taken (Lewis, 2006). Further south in Colombia, the sociologist Orlando Fals Borda (1977) long argued for the revolutionary potential of a 'people's science' – one that weaved together popular education, community organizing, and social science. Drawing on Lewin's action research, Fals Borda was the first to expressly articulate a praxis of *participatory* action research in his work with villagers in Boyaca, Colombia. Committed to the liberatory potential of PAR, Fals Borda led the organizing effort that resulted in the world's first conference explicitly about PAR in Cartagena in 1977.

At the heart of PAR's South American lineage is Paulo Freire's (1970) participatory approach to social change through conscientization, a process wherein people develop critical consciousness through a reflexive process of collective inquiry, reflection, and action on the economic, political, and social contradictions they are embedded in. Deeply committed to what Antonio Gramsci (1971) called 'organic intellectuals,' Freire, Fals Borda, and their colleagues argued that a research of the people by the people, that encouraged critical reflection on one's experiences, had the power to generate theory, design research, and engage action that could interrupt the oppressive conditions of the status quo.

PAR has continued to be developed in and across universities and communities in South America and around the world in countries such as Australia, Bangladesh, Canada, England, India, and the United States, among others.

Ethics

The epistemological stance of PAR has profound implications for rethinking ethical commitments which in turn, raise new questions for theory and practice. While many researchers choose to engage in PAR for ethical reasons, doing so does not circumvent ethical dilemmas (Manzo and Brightbill, 2007; Cahill et al., 2007; Tuck and Guishard, 2013). Indeed participatory research, informed by principles of inclusive democratic participation, explicitly engages the politics of collaboration, positionality, power, and accountability that are too often not addressed in traditional research practices. Participatory ethics are necessarily collective and take seriously questions of

collaboration in practice. Rather than top down, ethics are emergent and negotiated with participants. Guided by principles of inclusive democratic participation, a participatory ethics is characterized by mutual respect, relationality, humility, reflexivity; dignity, and collective action (cf Tuck and Guishard, 2013; Banks et al., 2011).

Motivated by a vision for 'what could be,' and the commitment to negotiating asymmetries of power, privilege, and knowledge production, participatory praxis throws into sharp relief the tensions between institutionalized and participatory ethics. Highlighting an epistemological shift, ethical questions that are traditionally founded upon the assumption of an individualized autonomy of institutional review processes are reassessed through a collective negotiation that reframes issues of consent, protection, and vulnerability within larger sociopolitical contexts. In this vein, participatory ethics are understood to be culturally and contextually specific, situated, and accountable to place and community (in all of its heterogeneity).

Ethics are traditionally framed around discussions of the overall harms and benefits of research, the rights of participants to information, privacy, confidentiality, and the integrity of researchers (Banks et al., 2011). PAR, however, opens up new and expansive ways of thinking about ethics, guided by its commitments to collaboration, transformative change, addressing unequal relations of power, and a retreat from a dispassionate stance. Beyond doing no harm, "a PAR inspired understanding of social justice suggests that it is in fact unethical to look in on circumstances of pain and poverty and yet do nothing" (Manzo and Brightbill, 2007: 35). Put another way, PAR recognizes research as a site of contestation in itself, and therefore participatory ethics are a commitment to disrupt the status quo, to challenge hegemonic practices and discourses, and to 'theorize back' (Tuck, 2009). In this sense, a participatory ethics can be understood as an ethical social scientific stance against neutrality. Informed by an 'ethic of care' in its most profound sense, participatory ethics reflect deep a commitment to justice and respect for relationships and humanity (Ellis, 2007).

Methodological Considerations and Commitments

The epistemological and ethical commitments of PAR fundamentally shape methodological and praxis decisions throughout the research process. PAR projects engage a wide range of methodologies for data collection and analysis, including both qualitative and quantitative approaches. At best, PAR designs include multiple and triangulated methods to capture interconnected individual, social, institutional, and cultural layers of the phenomena, being studied. Participatory methodologies include (but are not limited to) surveys, interviews, focus groups, archival data, maps, oral histories, digital stories, participatory video, photo-voice, participant observation, cross-site visits, 'stats in action,' and 'sidewalk science' (cf Stoudt and Torre, 2014).

While PAR projects are not restricted to particular methodologies, they share an orientation that informs decision-making throughout the research process. As a research practice *with*, rather than *for* or *on* communities, PAR revolves around a shared set of commitments for creating conditions of collaboration within research collectives. Articulations of these conditions differ depending on the situation and context but they all underscore the following commitments (cf 'Principles' www.publicscienceproject.org):

- to include knowledges and expertise that have been historically marginalized and delegitimized;
- to exchange expertise and share resources within the research collective;
- to an ongoing negotiation of issues of power and attention to vulnerability within the participatory collective and created by the research and associated actions;
- to creation of a research space wherein individuals and the collective can express their multiplicity and use this multiplicity to inform research questions, design, and analyses;
- to excavate and surface disagreements in the interest of consensus as a lens into larger social/political dynamics informing the research;
- to conduct intersectional analyses at the individual, social, historical, cultural, and institutional levels;
- to conceive multiple forms of action over the course of the PAR project;
- to an ongoing negotiation of conditions of collaboration.

The epistemological, methodological, and political commitments of PAR raises and complicates the questions of objectivity and validity that are arguably relevant to all social research, but that PARs make explicit. PAR challenges, redefines, and transforms traditional understandings of these concepts. To begin, approaching research methods through a PAR framework adopts what feminist scholar Sandra Harding (1993) calls 'strong objectivity,' which honors the rigor of situated knowledge and committing to exploring competing perspectives through democratic participation.

Building off of traditional conceptualizations, PAR reframes validity revising metrics of expertise and offering new definitions. First, engaging the iterative exchange between critical theory and research findings, PARs are concerned with *construct validity* that is the extent to which an analysis recognizes the impact of history and structures of injustice on individual and collective levels. *Ecological validity* is a new construct that theorizes the way a 'problem' can be understood at multiple scales and levels of analysis, from the intimate to the global, or the micro to the macro. *Expert validity* reflects deep participation, contesting and opening up traditional views of expertise, by engaging diverse standpoints while recognizing the relationship between situated knowledges and systems. Finally, *impact validity*, attending to what type of impact the research has on the injustice the research is centered around, is designed to be accountable and in solidarity with movements for social change (Torre et al., 2012; Fine, 2008). Breaking the monopoly on who holds knowledge and for whom social research should be undertaken, PAR offers new ways of thinking about methodologies, science, and expertise.

Purpose, Publics, and Products

While all research must ask questions of purpose, PAR features these questions explicitly from the start. Intertwined questions of purpose, publics, and products are revisited and

collaboratively interrogated throughout the PAR process reflecting the commitment to produce research that addresses urgent questions as defined by those most impacted. Indeed, it is the purpose of the PAR project that determines the design of the research and brings co-researchers together in the first place. Questions of purpose, publics, and products encouraged within PAR push the research collective to ask: What is the research trying to accomplish? What audiences is the research trying to engage? And, how might the research best communicate to a specific audience?

Participatory collectives attend to and negotiate these questions – often recognizing multiple perspectives on the goals of the project – that demand diverse publics, and therefore the development of a variety of research products. Multiple products not only provide different ways of speaking to different publics (be they academics, policymakers, young people, educators, etc.), they also create a way of attending to the 'thickness' of research and the different levels of analysis that were explored.

PARs are generally committed to making a meaningful contribution to social change beyond an 'armchair revolution' (Freire, 1970). This means that PAR collectives regularly attempt to reach publics beyond the academy. Products typically include: scholarly articles that speak to (or back to) ongoing academic debates; policy reports; popular journalism pieces; data posters, postcards, and infographics; performances and documentaries; websites and social media campaigns. Regardless of form, research collectives take seriously the political nature of knowledge production and the question of impact: How might the analysis inform a sense of responsibility and incite the possibility for change? What is the research asking audiences to do? Will interpretations be individually authored or collective voice? Who is made vulnerable by the research? What might be too sacred or dangerous to make public? And, finally, how might the research effectively provoke actions that feed organizing campaigns, theoretically reframe the issues, nudge those in power, and/or motivate audiences to shift how they think and act in the world? The contextually specific ways these questions are answered speak to PAR's commitments to blend systematic inquiry, democratic engagement, and liberatory organizing in order to engage research for justice (Cahill and Torre, 2007).

Future of the Field

Critical issues of funding, tenure, and promotion must be addressed if the field of PAR is to continue its growth within the academy. While disciplines such as public health have embraced PAR with robust funding streams dedicated for what is often called 'community-based participatory research' the CBPR, this is not true in the social sciences more generally. Despite a burgeoning interest across the disciplines, within the university questions remain in evaluation committees about 'impact factors' and how to value multiple authorship and research products that are not in the form of peer-reviewed journal articles. There are some positive recent developments however as there is a push toward civically engaged scholarship within the academy and for institutions of higher education to contribute to the communities they are located within – rethinking the role and moral responsibility of the academy in desperately unequal times. Communities are increasingly demanding reciprocity with university researchers and clarity with regard to the questions of purpose and publics issues that are well addressed by PAR projects. In addition, research centers are beginning to spring up that bridge universities and communities, some offering training institutes on PAR methodologies as well as supporting PAR projects. As a result of these trends, it is now standard to find PAR theory and methods included in volumes on research methodology, and feminist, critical, and community-based research approaches across the social sciences. While there is a way to go before PAR is fully embraced by the academy, there is a growing body of scholarship, and increasing interest in creating critical opportunities for PAR as public scholarship, since it offers a strategic and thoughtful approach to strengthening the social compact between the academy and larger society.

Partnership Formation and Dissolution in Western Societies

This article is a revision of the previous edition article by K. Kiernan, volume 16, pp. 11092–11099, © 2001, Elsevier Ltd.

Abstract

Partnership formation and dissolution in Western countries has changed dramatically over the last decades. Marriage has declined while cohabitation and childbearing in cohabitation has increased. Union dissolution, living apart together, and repartnering have become common. Despite the nearly universal increase in these behaviors, patterns of union formation continue to differ across Europe and the United States. This article briefly describes the correlates and consequences of these behaviors and the difficulties in disentangling selection effects and causality. It outlines the main explanations for developments in union formation and suggests historical, cultural, and legal factors that may account for country differences.

Over the past few decades, the process of partnership formation has become much more complex in most Western nations. No longer do individuals simply enter marriage and remain married for life. Instead, individuals are likely to enter into unmarried, coresidential relationships that may persist, convert to marriage, or end in dissolution. Individuals may experience a single union that lasts a lifetime or have multiple unions over the lifecourse. Marriage may occur early, be delayed until after childbearing, or never occur at all. Thus, the timing, duration, and repetition of cohabiting and marital unions have become very complex. Here, these developments and their implications are examined for a range of Western nations with a particular focus on Europe and the United States.

Partnership Formation

Marriage Trends

Since the 1970s, marriage rates in most Western countries have declined dramatically. In 27 countries of the European Union, the crude marriage rate fell from 7.9 marriages per 1000 inhabitants in 1970 to 4.4 marriages per 1000 inhabitants in 2010, equivalent to a 36% decline in the absolute number of marriages (Eurostat, 2013). Crude marriage rates in the US were considerably higher in 2010 at 6.8 per 1000 inhabitants (Centers for Disease Control, 2013). Although marriage rates have been declining across Europe, the US, and Australia, the rates of decline have differed substantially by region. Marriage rates first started declining in Sweden and Denmark in the late 1960s, declined throughout most of Western Europe in the early part of the 1970s, and began declining in the southern European countries (Spain, Italy, Portugal, and Greece) around the mid-1970s. Central and Eastern Europe, however, had only gradual declines in marriage rates until the collapse of socialism in the 1990s, when marriage rates plunged. Recently, marriage rates across Europe have stabilized at lower levels or even experienced small increases (Eurostat, 2013). In fact, in the late 1990s and 2000s, Sweden experienced a 'marriage revival,' with an upswing in marriage rates.

Some of the decline in marriage has been due to the postponement of marriage to older ages. In 1975, the average ages of first-time brides in Western Europe were clustered in the 22–24 years range; by the 2000s they were between 27 and 29 years. In Central and Eastern Europe, the mean age at marriage for women was between 20 and 24 years until the 1990s, when the mean age at marriage rose by about 2 years. The pattern of change was similar for men, but on average, men marry 2 years later than women, an age difference that has been fairly stable over time. As couples marry later in life, marriage rates may flatten or even recuperate. However, the decline in marriage rates is also due to the increase in unmarried partnerships that may be replacing marriage or never entering a partnership at all (*see* Transition to Adulthood).

Cohabitation

One of the most striking changes to partnership formation has been the rapid and nearly universal increase in cohabiting unions throughout Europe and the United States. A small percent of couples did live together without marrying before the 1970s, particularly after divorce, but the recent increase suggests that cohabitation is transforming the process of union formation. Over the past few decades, researchers have struggled to understand and classify cohabitation using a variety of comparison groups and criteria (Smock, 2000). Depending on criteria analyzed, cohabitation can be a prelude to marriage, a stage in the marriage process, an alternative to being single, an alternative to marriage, or even indistinguishable from marriage (Heuveline and Timberlake, 2004). Some research investigates whether cohabitation is an alternative to being single or married by analyzing individual characteristics and resources (Rindfuss and VandenHeuvel, 1990), or the duration of the union and whether it dissolves or transitions into marriage (Heuveline and Timberlake, 2004). Others have investigated the role of pregnancy (Raley, 2001) and childbearing (Perelli-Harris et al., 2012) in decisions to cohabit or marry. It is important to keep in mind that the meaning of cohabitation differs considerably based on social, cultural, religious, and policy context.

The Incidence of Cohabitation

Unlike marriage, which must be officially registered with state agencies, cohabitation is rarely officially recorded, although in

some countries partners can register their unmarried partnerships, which would be enumerated in official records. Within the past 10–20 years, however, cohabitation has also been recorded in housing registers in some Scandinavian countries. Most of the data on cohabitation in Europe come from surveys, which can be subject to recall error and vague definitions of what it means to be living with a partner. Nonetheless, survey data do provide general information about this behavior. The European Social Survey, which provides cross-sectional information on living arrangements in 2010, asked respondents living with a partner whether they are married, in a legally recognized partnership, or in a partnership not legally recognized (they could also report being separated or divorced). The category 'legally recognized partnership' differs by country. Some countries, such as Belgium, the Netherlands, and France, require partners to officially register their partnerships in order to gain rights. Other countries have no registration system, but respondents may perceive that their partnership is legally recognized. Whether the relationship is actually recognized in law differs by country and depending on policy area (Perelli-Harris and Sanchez Gassen, 2012). In some countries, respondents may think their partnership is legally recognized, even though they may not have the same rights and responsibilities as married couples. In addition, the law may differ for heterosexual and homosexual couples, with same-sex couples having access to legally recognized unions, but not marriage (Table 1 does not distinguish between hetero- and homosexual partnerships).

Table 1 shows the distribution of types of unions for respondents aged 15–45 currently living with a partner in 26 European countries in 2010. First note that the majority of respondents in most countries are married; only Sweden and Estonia have fewer than 50% of couples not married. Second, in most countries, few respondents report being in legally recognized unions, except in the Netherlands, where registered partnerships have become much more prevalent (20.55%) and Sweden, where over half (54.41%) report that their unions are legally recognized (nonetheless, not all laws in Sweden are the same for cohabiting and married respondents – see Perelli-Harris and Sanchez Gassen, 2012). A substantial proportion in most countries reports living in unions that are not legally recognized, ranging from over 40% in Scandinavia, around a third in Northern and Central Europe, to about a fifth in Eastern Europe, although Poland and Ukraine only have about 12% of respondents living in cohabitation. Some parts of Southern Europe, particularly Greece and Croatia, have fewer than 10% of couples living together without being married, indicating very low uptake of these new living arrangements. Overall, however, it is striking at how common cohabitation has become across Europe.

In order to better show the increase in cohabitation over time, Figure 1 shows the proportion of women who have ever cohabited for birth cohorts of women from 1930 to 1979 for a selected set of European countries and the US. The data come from nationally representative surveys in each country conducted between 2003 and 2010. Figure 1 demonstrates the diversity of behaviors across countries and differences in the rate of change; for example, the increase was very fast in some countries such as Norway and the UK, while much slower to increase in countries such as Bulgaria and the Netherlands.

Note that the percent of women ever cohabiting is higher than those currently living outside of marriage (shown in Table 1), suggesting that many women cohabit and then marry or experience cohabitation after divorce.

Type of First Partnership

Cohabitation is becoming increasingly prevalent as the way in which unions begin; couples often move in together before marriage rather than directly marrying. Column 1 of Table 2 shows the proportion of women who started their first partnership with cohabitation for cohorts born in the 1960s and 1970s. In most of Northern and Central Europe, direct marriage is becoming outdated: over 75% of unions start with cohabitation, especially those of the younger cohorts. In the United States for the 1970 cohort, nearly 70% of unions begin with cohabitation. In parts of Southern and Eastern Europe which traditionally had low levels of cohabitation, for example, Spain and Russia, nearly half of all unions now start with cohabitation. Even in parts of Europe where the diffusion of cohabitation was said to have stalled (i.e., Italy and Romania), a quarter of unions start with cohabitation. Note, however, that the 1970s cohort includes women who would have only been in their early twenties at the time of the interview, which may overestimate the percent cohabiting.

Figure 1 Proportion of women who ever cohabited by birth cohort. Note: weights applied where available. Sources: Generations and Gender Surveys in Austria (2008–09), Belgium (2008–10), Bulgaria (2004), Estonia (2004–05), France (2005), Italy (2003), Lithuania (2006), Norway (2007–08), Romania (2005), and Russia (2004); Fertility and Family Survey in the Netherlands (2003); British Household Panel Survey (2005–06); Employment, Family, and Education Survey in Poland (2006); Spanish Fertility Survey (2006); U.S. National Survey of Family Growth (2006–08).

Women who delay marriage may be more likely to directly marry, but we cannot know for sure until more recent data become available.

Duration of Cohabiting Unions

Although cohabitation is becoming the normative way of starting a union, marriage does still occur for the majority of couples in nearly all countries. Column 2 of Table 2 shows the proportion of women who marry their first partner within 5 years of starting to live together. For the 1960s cohort, more than half of women married their first partners within 5 years in all countries except France, Norway, and Spain. For the 1970s cohort, far fewer women had married their partners in most countries, but again it is important to note that results may not reflect ever marrying, because this younger cohort had less time to marry before the interview. In any case, in most countries, cohabitation continues to precede marriage rather than being a long-term living arrangement. In addition, first cohabiting unions also frequently dissolve within 5 years, as can be seen in column 3 of Table 2. This is particularly the case in the UK and the USA, where over a quarter of unmarried partnerships dissolve; these 'fragile' relationships have been frequently discussed in the U.S. literature (e.g., Carlson et al., 2004). However, around a third of cohabiting unions also dissolve in Norway, where cohabitation is usually considered a long-term relationship, and a quarter dissolve in Italy, where cohabitation is less frequently practiced. Hence, dissolution can be common in a country where cohabitation is widely practiced or in one where cohabitation is more select. To reiterate, this table demonstrates the diversity of union formation practices across Europe and the United States. Although direct marriage is clearly declining everywhere, what happens after entering cohabitation differs greatly by country.

Childbearing within Cohabitation

Along with the general increase in cohabitation, childbearing within cohabitation has been on the rise in nearly every Western country. Figure 2 shows the percent of first births in cohabitation for 14 countries of Europe and the United States. As with the overall trends in cohabitation, the largest increases have occurred in Norway, France, and Estonia. Sweden (not shown) also has had a large increase in the percent of births within cohabitation (over 50% of all births were in cohabitation in the 1990s: Kennedy and Thomson, 2010), as has eastern Germany (50% of first births occurred in cohabitation for the 1971–73 cohort: Perelli-Harris et al., 2012). Other countries in Europe have experienced moderate increases, so that in many countries one-quarter to one-third of births are in unmarried partnerships. Even countries such as Poland and Italy have experienced small increases. For example, in Italy in 1995–2003, 9% of births were to cohabiting women (Perelli-Harris et al., 2012).

The increase in childbearing within cohabitation indicates that the meaning and function of marriage is changing rapidly. Having children outside of marriage is increasingly accepted and most Western governments grant unmarried fathers the same rights and responsibilities as married fathers (Perelli-Harris and Sanchez Gassen, 2012). Nonetheless, cohabitation is not necessarily chosen as a long-term relationship type for raising children. The majority of women across Europe who

give birth within a union do marry at some point around the birth of a first child (Perelli-Harris et al., 2012). This finding suggests that marriage is not disappearing, but is being postponed to a later stage in family formation.

Who Cohabits?

Union formation not only varies across countries, but also within countries. Patterns of union formation are becoming more destandardized, with increasing heterogeneity in whether individuals cohabit, marry, dissolve their partnerships, or repartner. However, some trends are more likely to occur among certain subgroups of the population. For example, cohabitation is more likely to be practiced by those who are less religious and those who experienced parental divorce during childhood. In the United States, evidence shows that cohabitation is more likely to be practiced by African-Americans, as well as those who are less educated and have lower incomes (Kennedy and Bumpass, 2008). The association between cohabitation and education for other countries is mixed; some countries in Eastern Europe have a negative educational gradient of ever having cohabited, while some countries in Western and Central Europe have a positive educational gradient. The educational gradient for cohabiting at the time of birth, however, is more consistent: in eight countries of Europe women with lower education have higher rates of having a birth within cohabitation than women with higher education (Perelli-Harris et al., 2010). This finding suggests that although women may not differ by education upon entrance into cohabitation, more highly educated women are more likely to marry before the birth of a child.

Besides cohabitation becoming more common among certain groups in society, studies also show differences between cohabiting and married individuals. For example, cohabitors are more likely to keep their finances separate (Lyngstad et al., 2011) and have lower-subjective well-being (Soons and Kalmijn, 2009), lower relationship quality and less commitment to each other (Wiik et al., 2009). Cohabitors also have lower fertility, both first- and second-birth rates (Perelli-Harris, 2014). It is important to keep in mind, however, that differences between cohabiting and married couples could be due to the characteristics of those who cohabit. In addition, as discussed above, many cohabitors eventually marry, and their behaviors may become more similar to married couples over time. For example, women who have a first birth in cohabitation and then marry have similar second-birth rates to those who were married at first birth (Perelli-Harris, 2014).

Living Apart Together

Besides an increase in relationships in which unmarried couples live together, relationships in which unmarried partners live in separate households, or 'Living Apart Together' (LAT) relationships, are gaining visibility in Western countries. In the past, these relationships may have been considered 'going steady' or 'dating' relationships, but today LATs are usually considered to be more stable and may be facilitating the postponement of cohabitation or marriage. The reasons for couples to live apart are numerous, for example some young couples live apart because they attend school or have jobs in

Figure 2 Proportion of women with a first birth in cohabitation by birth cohort. Note: Weights applied where available. Sources: Generations and Gender Surveys in Austria (2008–09), Belgium (2008–10), Bulgaria (2004), Estonia (2004–05), France (2005), Italy (2003), Lithuania (2006), Norway (2007–08), Romania (2005), and Russia (2004); Fertility and Family Survey in the Netherlands (2003); British Household Panel Survey (2005–06); Employment, Family, and Education Survey in Poland (2006); Spanish Fertility Survey (2006); U.S. National Survey of Family Growth (2006–08).

different places or they may be unable to afford housing separate from their parents. Older couples may live apart after having been in previous unions to maintain autonomy and separate finances, or due to relationships with adult children. LATs can be difficult to study due to the ambiguity of the definition and meaning of these relationships. However, some researchers have analyzed survey questions to determine the prevalence of LATs. For example, in the UK in 2002–03 about 3 in every 10 of adults aged 16–59 who were neither cohabiting nor married reported having a regular partner living in another household (Haskey, 2005). This figure is very similar for those aged 23–70 in the United States in 1996 and 1998 (Strohm et al., 2009) and in Spain for those aged 15–49 in 1999 (Castro-Martín et al., 2008).

Partnership Dissolution

Divorce Trends

Over the past few decades, divorce has become much more common in Western countries (*see* Divorce, Sociology of). In most Western countries divorce has increased since the mid-1960s, but in some European countries (e.g., Malta and Ireland) divorce has only recently become legal. In the EU-27, crude divorce rates nearly doubled from 1.0 divorce per 1000 per inhabitants in 1970 to 1.9 divorces by 2009 (Eurostat, 2013). In the 1970s the highest divorce rates among the EU-27 were in the Baltics, especially Latvia (4.6) and Estonia (3.2), but Russia and the US also had high-divorce rates (3.0 and 3.5. divorces per 1000 respectively) (UN, 2009). The divorce rates in these countries increased even further throughout the 1980s, but declined in the 1990s and 2000s. By the late 2000s, however, the divorce rate had increased again slightly. While many other countries experienced steep increases, few had rates approaching those found in these high-divorce countries. Since the 1980s, Northern Europe has had crude divorce rates roughly between 2.0 and 3.0, while Western and Central Europe started out having more moderate divorce rates between 1.0 and 2.0, but with steep increases to over 2.0 in the 1990s and 2000s. Southern Europe and Ireland continued to have divorce rates lower than 1.0 until 2000, when Spain's divorce rate increased to 2.1. The most recent data from 2009 to 2011 show relatively high crude divorce rates throughout Europe, possibly due to the financial crisis. Note, however, that crude divorce rates are calculated per 1000 inhabitants and not per marriage and therefore may be influenced by changes in marriage rates and the age structure of the population.

Many studies have examined the correlates of divorce, but these tend to differ across countries and change over time. For example, Härkönen and Dronkers (2006) found that women with higher education had a higher risk of divorce in France, Greece, Italy, Poland, and Spain, but that there was no relationship in Estonia, Finland, West Germany, Hungary, Latvia, Sweden, and Switzerland and a negative relationship in Austria, Lithuania, and the United States. In the US, divorce rates are diverging between higher and lower educated women, with college-educated women experiencing a decline in divorce rates while women with less than a college degree continuing to have high-divorce rates (Martin, 2006).

Other correlates of divorce include early marriage, poverty, having no religious affiliation, living in an urban area, parents' divorce, previous divorce, and having no common children (see Amato, 2010; Amato and James, 2010; Lyngstad and Jalovaara, 2010 for reviews). Wagner and Weiß (2006) found that in many European countries, premarital cohabitation was associated with divorce; however, this relationship may change over time and space. Liefbroer and Dourleijn (2006) found that couples who premaritally cohabited had higher risks of union dissolution only in countries where premarital cohabitation is relatively rare or very common. In addition, research has found that wives' employment and earned income are positively associated with divorce in the US and Europe, however this relationship may be moderated by gender attitudes,

marital quality, and division of household labor (Amato and James, 2010).

Many studies have shown that divorce has negative consequences, both on individuals and their children (see Amato and James, 2010). Research from Europe and the United States shows that divorced individuals have worse mental and physical health than their married counterparts and often die earlier. Children with divorced parents, on average, score worse on a number of emotional, behavioral, and academic outcomes and have weaker ties to their parents. As adults, they have poorer physical health and experience more problems with their own relationships. However, it is difficult to tell whether divorce causes these negative consequences or whether these outcomes are due to selection effects, such as other characteristics or factors that may cause both the divorce and the poor outcomes. Thus, the outcomes may have been similar if the couple stayed together rather than divorcing.

Union Dissolution

Not only has there been an increase in marital unions ending in divorce, relationship breakdown in general has increased, due to the frequent dissolution of cohabiting unions, as discussed above. As seen in **Figure 3**, the percent of women who have ever experienced separation from either a marital or nonmarital relationship has been increasing throughout Europe. In Norway, Estonia, and the UK, over 40% of women born in 1960–69 have experienced union dissolution. In Spain, Romania, and Italy, the proportion is substantially lower, but still around 10%. Thus, declines or the stabilization in divorce rates may be due to increases in the number of cohabiting couples that separate before marrying.

Remarriage and Repartnering

Along with the increase in union dissolution, entering into second and higher order partnerships has become more common. These partnerships are more likely to be cohabiting unions, rather than direct marriages. The partners frequently have children from previous relationships resulting in stepfamilies and blended families. Often the meaning of stepfamily relationships is less certain than for first marriages, especially when children are involved (Sweeney, 2010). Hence stepfamilies are considered to be 'incompletely institutionalized,' due to the ambiguity in the role of stepparents toward children, rights and obligations of stepfamily members, and even the names that stepchildren should call their stepparents. A growing number of studies have provided information on the characteristics, determinants, and outcomes associated with repartnering (see Sweeney, 2010 for a review). Often this research is complex, because it can investigate characteristics of the individual, the couple – in which either or both are remarried – or the incidence of multiple or serial partnerships. More research has been conducted on remarriage and stepfamilies in the US, but research in Europe is increasing and sometimes has different outcomes. For example, Sweeney (2002) found a positive association between educational attainment and remarriage for U.S. women, but studies in Europe and the US found either no relationship or a negative association with repartnering in general (see Sweeney, 2010). In most countries, second and higher order marriages are more likely to dissolve than first marriages. As with divorce and cohabitation, it is important to examine the selection processes that lead to remarriage and repartnering to better understand how family structure influences outcomes.

Explanations for Changes in Partnership Behavior

Over the past few decades, several explanations have emerged for the changes in union formation. The most common explanation is the Second Demographic Transition (Van de Kaa, 1987; Lesthaeghe, 1983). Broadly speaking, the Second Demographic Transition describes changes in family

Figure 3 Proportion of women ever separated or divorced from marital or nonmarital unions, by birth cohort for selected countries of Europe. Note: Weights applied where available. Sources: Generations and Gender Surveys in Austria (2008–09), Bulgaria (2004), Estonia (2004–05), France (2005), Italy (2003), Lithuania (2006), Norway (2007–08), Romania (2005), and Russia (2004); Fertility and Family Survey in the Netherlands (2003); British Household Panel Survey (2005–06); Employment, Family, and Education Survey in Poland (2006); Spanish Fertility Survey (2006).

behavior such as the postponement of marriage, the increase in cohabitation, and the gradual decoupling of marriage and fertility. Proponents of the Second Demographic Transition explanation argue that changes in behavior are the result of ideational change, including shifts in values toward greater autonomy, individualism, and rejection of authority and institutions such as marriage (Lesthaeghe, 2010). This explanation also suggests that family change is a result of the increase in female labor force participation and women placing a greater emphasis on their career, an idea also posed by Becker (1981) as an economic explanation for the 'erosion of marriage.' Implicit in these explanations is that the more highly educated are the forerunners of these new behaviors.

Other explanations have proposed that changes in family formation are due to different social and economic factors, such as increases in economic uncertainty, risks in the labor market, or inequality. Oppenheimer et al. (1997) critiqued the idea that women's independence was responsible for declines in marriage and proposed that young men's uncertain economic position was responsible for the shift from marriage to cohabitation. A range of evidence from the US and Europe supports this theory by showing that men's unemployment lowers the probability of marriage and vice versa (see Kalmijn, 2011). In addition, the negative educational gradient of childbearing within cohabitation shows that highly educated women are more likely to marry before having a birth than lower educated women (Perelli-Harris et al., 2010). These findings suggest that individuals with less education and/or facing economic difficulties may be choosing temporary, flexible arrangements rather than committing to marriage. In general, these changes may be a sign that family formation behavior is diverging between social strata, with the highly educated more likely to postpone marriage and childbearing and the lower educated more likely to have early births, bear children outside of marriage, and divorce (McLanahan, 2004). Evidence from the United States supports McLanahan's concept of 'diverging destinies,' indicating, for example, that cohabitation is associated with lower education, violence, and abuse, and that the children born into these unions tend to have lower well-being and worse psychological and academic outcomes. The evidence for these diverging trends in other countries, however, is far less extensive.

As described above, partnership formation and dissolution differs dramatically across Europe and the United States. Some studies have examined the underlying reasons for these differences; for example, Kalmijn (2007) found that countries with a higher proportion of women in the labor force had lower marriage rates and higher divorce and cohabitation rates, while countries with a higher percent belonging to a church had higher marriage rates and lower divorce rates. However, these simple relationships mask complex differences across countries, differences that reflect entrenched historical and cultural patterns. For example, Reher (1998) argued that in northern European countries 'weak family ties' lead to early home-leaving and high levels of cohabitation, while in southern European countries 'strong family ties' encourage marriage and oppose divorce. Western and Eastern Europe also have historical differences in household formation patterns, with Eastern Europe characterized by early, universal marriage, and Western Europe typified by later age at marriage and a substantial proportion never marrying (Coale, 1992). These historical norms and values continue to influence partnership formation today. In addition, welfare states and legal systems can shape union formation; Western European countries fall along a continuum from countries with laws that treat cohabiting and married couples the same to those that privilege marriage and the breadwinner model (see Perelli-Harris and Sanchez Gassen, 2012). While it is difficult to know to what extent lawmakers are responding to changes in demographic behavior, the laws themselves may encourage citizens to choose one type of union over another. All in all, understanding differences across countries requires a multifaceted approach that incorporates social, economic, legal, and historical explanations.

Conclusion

Changes in partnership formation and dissolution have been occurring rapidly in nearly every Western country. It is difficult to know, however, what these changes imply. Are cohabitors simply postponing marriage to later in the lifecourse or is cohabitation replacing marriage altogether? Will marriage rates level off, or will marriage disappear? Will unions become increasingly more unstable, or will there be a return to greater stability? Are all countries on a similar trajectory toward relationship transformation or will some maintain their traditional, stable patterns? And finally, will patterns of family formation become markers and reproducers of inequality, with the more advantaged choosing marriage and the less advantaged cycling through less stable relationships? Future research needs to shed light on the answers to these and many related questions.

Abstract

After a short traditional discussion of parts of speech, the present article will start out from a definition of four prerequisites that are relevant for the definition of parts of speech. These prerequisites will be used for comparing the two most comprehensive typological approaches to parts of speech by Croft (1991, 2000, 2001) and Hengeveld (1992, 2013). These approaches are then checked against three languages whose parts-of-speech systems have been described as typologically remarkable in the literature (classical Nahuatl, Tagalog, Tongan). A short conclusion summarizes these findings.

Introduction: Traditional Word Classifications

The classification of words has a long tradition. Dionysios Thrax (second century BC, Lallot, 1998), who was the first writer of a grammar in Europe and who summarized several centuries of Greek reflections on language before his time, already had a term for 'parts of speech' (The Greek term used by Dionysios Thrax was *mér-ē lóg-ou* [part-NOM:PL:NEUTR speech-GEN:SG:MASC] 'parts of speech.'). In his *téxnē grammatikē* 'Art of Grammar,' he defined the following eight parts of speech: nouns, verbs, participles, articles, pronouns, prepositions, adverbs, and conjunctions. With the exception of participles, these parts of speech are still relevant in most traditional grammars of English and many other languages. The following 10 parts of speech are the ones that are most commonly used in contemporary grammatical descriptions (Haspelmath, 2001). Each part of speech is illustrated by a few words from English.

1. Noun: *tiger, book, wind, departure, movement, carelessness*
   Verb: *know, come, push, give*
   Adjective: *good, red, happy, Russian*
   Adverb: *well, quickly, desperately, fortunately*
   Pronoun: *I, you, he, she*
   Adposition (preposition, postposition): *in, on, for, because of*
   Conjunction: *and, or, if, because*
   Numeral: *one, two, twenty, five hundred*
   Article: *the, a*
   Interjection: *ouch, tut-tut, shh, yeah*

The parts of speech listed in (1) do not all have the same size. There are open word classes that accept new members and comprise large numbers of words, and there are closed word classes consisting only of a small and fixed number of words. Verbs, nouns, and in some languages also adjectives and adverbs are open-class categories; the remaining parts of speech are closed-class categories. The individual members of the open-class categories occur comparatively rarely in discourse, while the members of the closed-class categories are rather frequent, first of all if they express a grammatical function (pronouns, adpositions, conjunctions, articles). The distinction between content words and function words covers a similar range of parts of speech. Verbs, nouns, adjectives, and adverbs denote individual concepts and are thus called 'content words,' while the 'functional words' stand for grammatical functions. Due to processes of grammaticalization, defined as the development of grammatical markers out of full words, the distinction between content and functional words is sometimes unclear. The class of auxiliaries is not part of the Greek and Roman tradition and this may well be

the reason why it is usually not listed as a separate word class, even though the auxiliaries *be* and *have* (*She **is** swimming. He **has** come.*) and their equivalents in other languages are very important function words.

The traditional criteria for distinguishing parts of speech are a combination of semantic and formal (morphological and syntactic) criteria. Attempts to define word classes purely in terms of semantics are too simplistic and can easily be falsified. Thus, a definition like 'nouns denote things, persons, and places' is disproved by a word like *movement*, which is a noun but refers to an action. The definitions of 'verbs denote actions and processes' and 'adjectives denote properties' run into similar problems (cf *know*, *exist* for the former and *urban*, *Bavarian* for the latter). The traditional formal criteria are based on distribution, i.e., the morphosyntactic environments in which an individual word with its semantics can occur. The formal criteria for defining verbs are morphological criteria like the compatibility with markers for tense, aspect and mood, markers of polarity (negative vs affirmative), of agreement (with subject and sometimes other categories like direct and indirect objects for person, number, and gender) and of valency change (passive, antipassive, causative, anticausative, middle, reciprocals). Syntactically, verbs can form the head of verbal phrases and they are characterized by their elaborate argument system. While other parts of speech can have maximally one argument, verbs can have one (intransitives: *sleep*), two (transitives: *hit*), or three arguments (*give*). Nouns are often characterized by morphological markers of case (nominative, accusative, ergative, absolutive, dative, etc.), number (singular, plural, dual, trial, paucal), gender (masculine, feminine, neuter), definiteness/indefiniteness, and possessor (cf Turkish *ev-im* [house-POSS:1.SG] 'my house'). Syntactically, nouns can take the head position of noun phrases and the argument positions of verbs. In addition, they are often combined with words like demonstratives or articles and they are the antecedents of pronouns and reflexives. Adjectives are characterized in some languages by special morphological forms or by specific syntactic constructions. English uses both expression formats, depending on the individual adjective. With adjectives like *happy*, the comparative and the superlative are formed morphologically (e.g., *happier*, *happiest*), while adjectives like *intelligent* express the same grammatical functions syntactically (e.g., *more intelligent*, *most intelligent*). In addition, adjectives cannot only occur in comparative constructions but also as modifiers of nominal heads. Finally, adverbs are the most heterogeneous category. In a strict definition, they modify verbs as *quickly* in *he runs quickly*. Morphologically, they are often unmarked (German: *Er singt schön* [he sing beautiful:ADV] 'He sings beautifully') but they can also have a specific marker (cf English *-ly*). A closer look at English *-ly* reveals that there are many other words marked by *-ly* whose scope is beyond the verb in its function as a predicate. Ramat and Ricca (1998) discuss the following types in their comparative study of adverbs in European languages: predicate adverbs that follow the strict definition, event adverbs (e.g., *obligatorily*, *rarely*, *yestereday*, *often*), propositional adverbs (e.g., *probably*, *unfortunately*, *cleverly*), and speech-act adverbs (e.g., *briefly*, *frankly*).

Parts-of-speech definitions of the above type are problematic for at least two reasons. (1) The generality problem is due to the language specificity of formal criteria based on expression formats for individual grammatical categories. Many languages have no articles or verb agreement. Due to differences like these, the formal criteria can be used at best for individual languages and are of little use for cross-linguistically valid universal definitions. (2) The subclass problem arises from the difficulty of deciding which of the language-particular criteria should be used for word-class definition. As was discussed above, adjectives can be defined by the presence of comparative morphology or by a syntactic comparative construction. In the case of English, one would have to distinguish between two subclasses of adjectives because the language uses both expression formats. Even though it is generally agreed that this is not sufficient for postulating two subclasses, the theoretical foundations for such a conclusion are anything but clear.

Criteria for Defining Parts of Speech

The current discussion on universally applicable criteria for the cross-linguistic definition of parts of speech is based on the following four prerequisites (Sasse, 1993b, pp. 196–201; Bisang, 2011, p. 281):

- semantic criteria;
- pragmatic criteria/criteria of discourse function;
- formal criteria (morphology, syntax);
- distinction between lexical and syntactic levels of analysis.

As will be seen in the Approaches to Parts of Speech and Short Case Studies and Problems sections, all four prerequisites are relevant for a universal assessment of parts of speech. The present section will only discuss each prerequisite individually from the perspective of the open-class categories of nouns and verbs.

Langacker's (1987) notional description of nouns and verbs is probably the most elaborate semantic approach to parts of speech. His definition of nouns is based on the concept of the REGION, which is conceived of as 'a set of interconnected entities' (Langacker, 1987, p. 62). Since nouns designate REGIONS, they are stable through time (static) and holistic. Verbs are defined as processes. They evolve through time state by state in "successive transformations which derive each component state from its predecessor" (Langacker, 1987, p. 74). In spite of its thoroughness, this approach cannot avoid the shortcomings of purely semantic definitions and it does not offer discovery procedures for parts-of-speech identification (Sasse, 1993a, p. 649). Another problem that concerns almost all definitions of semantic criteria with the exception of Dixon (2004) was pointed out by Wierzbicka (2000). Semantic criteria like object versus action or region versus process are too general because one cannot just take any object-denoting or action-denoting lexeme that belongs to these concepts (e.g., *parrot* or *grovel*) for testing word-class membership across languages. Many languages simply do not have a corresponding word. For that reason, the cross-linguistic assessment of parts-of-speech distinctions must be based on 'genuinely universal linguistic prototypes' (Wierzbicka, 2000, p. 288).

Hopper and Thompson (1984, p. 708) see the semantic properties of nouns and verbs as "derivative of (and perhaps even secondary to) their discourse roles." From such

a perspective, the prototypical discourse function of nouns consists in the introduction of participants and their deployment in the ongoing text. For that purpose, nouns must show continuity of identity and this, in turn, depends on time stability. Verbs prototypically "assert the occurrence of an event" (Hopper and Thompson, 1984, p. 708) and thus reply to the question 'What happened?' They can occur in many contexts in which their categoriality is reduced. Hopper and Thompson (1984) discuss stativity, irrealis, negation, serial verbs, compound verbs, and dependent clauses. From a broader perspective, nouns and verbs are associated with information structure and its categories of topic (nouns) and comment (verbs).

The importance of the morphological and the syntactic form in which the relevant semantic and pragmatic criteria are expressed is undisputed. It plays a crucial role in the traditional approach (Introduction: Traditional Word Classifications section) as well as in the more recent typological approaches discussed in the Approaches to Parts of Speech section. Even Dionysios Thrax clearly mentions morphological criteria (the expression of case, number, and gender), a fact that is missed by his critics who state that his definitions are purely semantics-based (Bisang, 2011, p. 280).

Most linguistic theories take it for granted that there is a perfect match between the lexicon and syntax. The lexicon consists of lexemes that are specified for certain word classes (N, V, etc.) and the syntactic structures are derived from these properties (N projects into NP, V projects into VP; cf Sasse, 1993a,b; Broschart, 1997). This generalization seems to hold for the majority of languages but there are two ways in which languages may violate this perfect match. Either they have only one open word class which basically encompasses all content words (cf the Extremely Rigid section on classical Nahuatl and Tagalog) or their lexical items lack parts-of-speech specification in the lexicon (cf the Contentives: The Case of Tongan section on Tongan). The latter type is sometimes discussed under the term of 'precategoriality' (Bisang, 2008, 2011).

Approaches to Parts of Speech

Croft (1991, 2000, 2001)

Croft (1991, 2000, 2001) offers a solution that significantly minimizes various shortcomings of earlier approaches. These shortcomings are due to general problems associated with the distributional analysis and the two perspectives of 'lumping' and 'splitting.' The distributional method has to face at least two problems. One of them is that a construction for determining word class in one language is not available in another language (cf the Introduction: Traditional Word Classifications section). The other problem is that parts-of-speech behavior in one construction is not sufficient. Individual words may well obscure parts-of-speech distinctions in the compatibility with one construction, but that does not imply the pervasiveness of that property across other constructions. Croft (2000, pp. 73–75) illustrates this fact with data from Makah as it is described by Jacobsen (1979). In the following example from this Nootka language, the inflectional marking of predicates is characterized by obligatory person marking (1.SG/3.SG) and by modality (IND = indicative). Even though inflectional verb morphology is quite complex in Makah and in Nootka in general, the glosses to the clause-initial predicate in the second line of examples (2a–d) indicate that this morphology is compatible with words denoting actions like 'to point' (2a), objects like 'white man' (2b), properties like 'to be big' (2c), and with adverbs like 'still' (2d):

2. Makah (Jacobsen, 1979, p. 110–111; from Croft, 2000, p. 73 and 2001, p. 30):
   a. k'upšil baʔas ʔuyu·q.
      point:MOM:IND:3 house OBJ
      'He's pointing at the house.'
   b. babałdis.
      white.man:IND:1.SG
      'I'm a white man.'
   c. ʔi·ʔi· X̣^{W} ʔi.
      big:IND:3
      'He's big.'
   d. hu ʔaxis haʔuk^{w} ap.
      still:IND:1.SG eat:CAUS
      'I'm still feeding him.'

As Croft (2000, pp. 73–76; 2001) points out, the data in (2) do not support the conclusion that Makah lacks any major parts-of-speech distinction. As he illustrates, the same words show clear distinctions in other constructions. For that reason, he concludes that it is possible to identify nouns, verbs, adjectives, and even adverbs and auxiliaries in Makah (for examples with significantly different marking patterns, cf the case studies in the Short Case Studies and Problems section).

A complete distributional analysis that integrates all possible compatibilities "provides the complete picture of the grammatical patterning of a language" (Croft, 2000, p. 76). This picture is extremely complex and fine-grained. Depending on the perspective of the individual approach to the definition of parts of speech, one can either ignore important distributional patterns and thus lump various subclasses together into a more general class (e.g., by defining Makah word classes only on the basis of the inflectional marking in (2)) or one can split the more general classes into subclasses by integrating data on more distributional environments. Ultimately, both perspectives are unsatisfactory. To avoid the problems of lumping and splitting, Croft offers his own construction-based universal theory.

Croft's theory understands the word classes of nouns, verbs, and adjectives as universal categories rather than as language-particular categories and thus takes a view that is diametrically opposed to most other approaches. In his view, nouns, verbs, and adjectives are typological prototypes that can be situated within a conceptual space that consists of three semantic classes and three pragmatic functions. The three semantic classes are objects, properties, and actions. The semantic classes form the vertical dimension of the conceptual space and are combined with the three pragmatic functions of reference, modification, and predication that take the horizontal dimension (cf **Table 1**). The pragmatic categories are defined as follows (also cf Bisang, 2011, p. 289). Predication is "what the speaker intends to *say about* what he is talking about (the referent)" (Croft, 1991, p. 52). The function of reference "is to get the hearer to identify an

Table 1 Croft's conceptual space for parts of speech

	Reference	*Modification*	*Predication*
Objects	*Object reference:* UNMARKED NOUNS	*Object modifier:* genitive, adjectivalization, prepositional constructions (cf Engl. *of N*)	*Object predication:* predicate nominals, copulas
Properties	*Property reference:* de-adjectival nouns	*Property modifier:* UNMARKED ADJECTIVES	*Property predication:* predicate adjectives, copulas
Actions	*Action reference:* nominals, complements, infinitives, gerunds	*Action modifier:* participles, relative clauses	*Action predication:* UNMARKED VERBS

Adapted from Croft, W.A., 1991. Syntactic Categories and Grammatical Relations: The Cognitive Organization of Information. Chicago University Press, Chicago, 53/67; Croft, W.A., 2000. Parts of speech as typological universals and as language particular categories. In: Vogel, P.M., Comrie, B. (Eds.), Approaches to the Typology of Word Classes. Mouton de Gruyter, Berlin, 89; and Croft, W.A., 2001. Radical Construction Grammar. Syntactic Theory in Typological Perspective. Oxford University Press, Oxford, 88/92.

entity as what the speaker is talking about" (Croft, 1991, p. 52). Modification is defined as an 'accessory function to reference and predication' because it is either a more specific instrument for identification in the case of restrictive modification or an instrument that provides a secondary comment in the case of unrestrictive modification (Croft, 1991, p. 52).

Each of the nine cells within the conceptual space stands for a type of construction. The terms for these construction types are given in italics. For each type, some individual constructions are listed in normal print.

Parts of speech manifest themselves within this space through markedness patterns of function-indicating morphosyntax in individual languages. In this context, markedness is seen as a universal property of conceptual categories (cf Croft, 2003, pp. 87–101, 110–117 on 'typological markedness'). Thus, a certain grammatical category is expressed with a certain degree of overt morphosyntactic markedness relative to other categories. In the above conceptual space for parts of speech, three combinations of pragmatic function and semantic class are prototypically unmarked. These same combinations also constitute parts of speech universally:

3. Croft (2000, p. 88):

noun = reference to an object
adjective = modification by a property
verb = predication of an action

This can be illustrated by a few examples from English. An object-denoting lexeme like *boy* tends to be less marked if it is in the pragmatic function of reference (*boy*) than if it is in the function of modification (*of a boy, the boy's, boyish*) or in the function of predication (*is a boy*). Similar statements are possible for property-denoting lexemes in the function of modification and action-denoting lexemes in the function of predication.

In Croft's (2000, p. 89) typological view on marking, "the structural coding criterion specifies only that the marked member is encoded by *at least as many* morphemes as the unmarked member." Thus, Croft's theory only excludes cases in which an unmarked member is expressed by more morphemes than a marked member. Equal marking and zero marking across neighboring cells are possible. In other words, the conceptual space of parts of speech predicts that unmarked combinations cannot be marked by more morphosyntactic material than the typologically marked combinations. It excludes a language in which predication of actions is expressed by a copula, while predication of properties and/or objects has no morphosyntactic marking.

From the perspective of the four prerequisites (Criteria for Defining Parts of Speech section), Croft's theory is characterized by the absence of the distinction between lexical and syntactic levels of analysis (fourth prerequisite). This is in line with his perspective of Radical Construction Grammar (Croft, 2001), which rejects the existence of universal categories (e.g., syntactic categories like N and V) and takes constructions as the basic primitive units of syntactic representation.

Functional Grammar (Hengeveld, 1992, 2013)

Hengeveld's (1992, 2013) approach to parts of speech is situated in the framework of Functional Grammar. He classifies basic and derived lexemes according to their formal behavior within a four-slot space formed by two parameters with two values each. One parameter involves the opposition between predication and reference, the other between heads and modifiers (cf **Table 2**).

The definition of parts of speech within the above table depends on markedness and on the basic question of whether a lexeme requires lexical or syntactic derivation for being accepted in the individual cells. Individual lexemes can be either rigid or flexible. A rigid parts-of-speech system is characterized by classes of lexemes that are tied to a single cell and require additional marking to be used in other functions. In Hengeveld's (1992, 2013) analysis, English is such a language. It displays separate lexeme classes of verbs, nouns, adjectives, and manner adverbs (this approach is only concerned with manner adverbs or MAdv). Thus, a verb like *sing* in (4) is used as the head of a predicate phrase. If it takes another functional slot, it is more marked. For the function of a referential head, it needs ablaut (*song*). In the two modifier functions, *sing* gets the form of *sing-ing* if it modifies a referential phrase and (*by*) *singing* if it modifies a predicate phrase.

Table 2 Lexemes and functions

	Head	*Modifier*
Predicate phrase	V	MAdv
Referential phrase	N	Adj

Hengeveld, K., 2013. Parts-of-speech systems as a basic typological determinant. In: Rijkhoff, J., Van Lier, E. (Eds.), Flexible Word Classes. Typological Studies of Underspecified Parts of Speech. Oxford University Press, Oxford, p. 32.

4. The tall$_{A}$ girl$_{N}$ sings$_{V}$ beautifully$_{MAdv}$.

Nouns are heads of referential phrases, adjectives are modifiers of referential phrases, and manner adverbs are modifiers of predicate phrases. Languages whose lexemes are rigid in all four functions are called 'differentiated' by Hengeveld (1992, 2013). A flexible parts-of-speech system is characterized by classes of lexemes that can be used in more than one cell without any difference in markedness. In the most extreme case, there is only one class of lexemes that covers all four cells. As will be seen in the Contentives: The Case of Tongan section, Tongan comes close to this type, which is called 'contentive.' Classical Chinese (Bisang, 2008) also belongs to this type.

The four functions in **Table 2** form a hierarchy, the parts-of-speech hierarchy as claimed by Hengeveld (1992) and Hengeveld et al. (2004):

5. Head of predicate phrase > Head of referential phrase > Modifier of referential phrase > Modifier of predicate phrase

The hierarchy determines the likelihood with which a language develops specialized classes of lexemes. The more to the left a function is in (5), the more likely it is that a language has a specialized class of lexemes. The hierarchy is implicational. Thus, it predicts for example, that a language with a specialized class for the expression of 'modifier of referential phrase' (adjective) also has specialized classes for 'head of referential phrase' (noun) and 'head of predicate phrase' (verb).

This hierarchy plus the distinction between flexible, differentiated, and rigid languages yields seven possible parts-of-speech systems summarized in **Table 3**. There are three different types of flexible systems (types 1–3), three different types of rigid systems (types 5–7), and the maximally rigid type called 'differentiated' (type 4).

In Croft's (2000, 2001) analysis, this system clearly sides with the lumpers that disregard various facts. This can be illustrated by the following example from Tongan that is discussed by Hengeveld (1992, p. 66) and Croft (2000, p. 70; 2001, p. 68):

6. Tongan (Tchekhoff, 1981, p. 4):
   a. na'e **si'i** 'a e akó.
      PST small ABS ART school
      'The school was small.'
   b. 'i 'ene **si'í.**
      in POSS:3:SG childhood
      'in his/her childhood'
   c. na'e ako 'a e tamasi'i **si'i** iate au.
      PST study ABS ART child small LOC 1.SG
      'The little child studied at my home.'

As the above example shows, the lexeme *si'i* 'small' can take the verbal position (6a), the nominal position (6b), and the adjectival position (6c) without any change in markedness. Thus, it counts as a highly flexible lexeme. As Croft (2000, 2001) points out, a closer look reveals that the meaning of *si'i* in these individual functions cannot be regularly derived at least in the case of 'be small' (6a) versus 'childhood' (6b). Since it has underivable meanings in the individual functions, Croft argues that one should still analyze it in terms of different lexemes from a more splitting perspective (but cf the Contentives: The Case of Tongan section).

Table 3 Parts-of-speech systems

PoS system		*Head of predicate phrase*	*Head of referential phrase*	*Modifier of referential phrase*	*Modifier of predicate phrase*

	7	Verb			

Hengeveld, K., 2013. Parts-of-speech systems as a basic typological determinant. In: Rijkhoff, J., Van Lier, E. (Eds.), Flexible Word Classes. Typological Studies of Underspecified Parts of Speech. Oxford University Press, Oxford, p. 36.

Hengeveld's (1992, 2013) lumping tendency has the positive effect of leading to a number of predictions concerning correlations between the parts-of-speech system of a language and other properties of its grammar. Hengeveld (2013) groups them under four headings of (1) identifiability, (2) integrity, (3) unity, and (4) pervasiveness. Some of these generalizations will be briefly sketched here (cf Hengeveld, 2013 for a comprehensive summary):

Identifiability

In a rigid system, the functional slot to which a class of lexemes belongs is clearly determined. In flexible systems, the lexical information is insufficient for uniquely identifying the function of a lexeme. Thus, in a language of type 1 (contentive), the lexical information provided by a lexeme is underspecified for the categorical status of the phrase in which it occurs as a predicate phrase or as a referential phrase within a sentence. This lack of identifiability in flexible systems is compensated by less freedom of word order in flexible systems. More specifically, languages of type 1 are verb-first or verb-final languages, they do not have predicate medial basic word order. Only with these word orders is it possible to clearly associate that position with the predicate phrase (but cf Conclusion).

Integrity

The flexibility of a lexeme class would be significantly restrained if its shape would depend on specific functional environments. Thus, "flexible lexemes may be expected not to show morphologically conditioned stem alternation, such as morphophonological variation, irregular stem formation, or suppletion" (Hengeveld, 2013).

Unity

The functional elasticity of flexible lexemes crucially depends on the phonological, morphological, and semantic unity or homogeneity of a lexical class. This homogeneity is hampered if flexible classes are divided into subclasses. Thus, systems of

subclassification like declension and conjugation classes are unlikely to occur in flexible languages. An example of semantic subclassification is number. Flexible lexemes are not intrinsically specified for singular (or plural) number.

Pervasiveness

The predictions discussed under this heading deal with the pervasiveness of flexibility through different levels of analysis. The general prediction is that flexibility decreases from lower to higher levels. In languages with flexible systems, the parts-of-speech system used for the expression of subordinated clauses (e.g., the use of a single construction type for relative clauses and complement clauses) tends to be less flexible than the parts-of-speech system at the level of the matrix clause (Van Lier, 2009).

Hengeveld's (1992, 2013) approach includes all four prerequisites. The opposition between predication and reference covers the semantic and the pragmatic criteria. The formal criteria are reflected in the markedness patterns associated with the lexeme classes. The lexemes with their specific forms are mapped onto the head or the modifier positions of the predicate phrase and the referential phrase. Thus, the distinction of the two levels of lexicon and syntax is a crucial component of this approach.

Short Case Studies and Problems

The approaches of Croft (section Croft (1991, 2000, 2001)) and Hengeveld (section Functional Grammar (Hengeveld, 1992, 2013)) differ with regard to the fourth prerequisite (Criteria for Defining Parts of Speech section). From Croft's (2001) perspective of Radical Construction Grammar, there are no universal syntactic categories onto which lexical items have to be mapped, while Hengeveld's approach integrates the mapping of lexemes onto the positions of heads and modifiers. As was mentioned at the end of the Criteria for Defining Parts of Speech section, there are two types of parts-of-speech systems which can only be fully understood if the fourth prerequisite is integrated. In one type, there is only one open word class that covers all content words. This type is captured by the extremely rigid type 7 in Hengeveld's terminology. The other type is characterized by the absence of parts-of-speech specification in the lexicon and is reflected in Hengeveld's contentive type with its extremely flexible system.

In both types, the noun/verb distinction does not work on the syntactic level. In the extremely rigid type, there is only one open word class, while there is no noun/verb distinction in the lexicon of the contentive type. The first type will be illustrated by examples from classical Nahuatl (Omnipredicativity in Classical Nahuatl section) and Tagalog (Tagalog And The Parts-Of-Speech Hierarchy section), the second type by examples from Tongan (Contentives: The Case of Tongan section). Classical Chinese as another example of the second type will not be discussed here (Bisang, 2008). As will be seen, the languages that belong to these types still offer quite a few challenges to current approaches to parts of speech. Most remarkably, the morphology of most of them still shows noun/verb distinctions even if the lexicon/syntax mapping disregards them (On the Role of Morphology section).

Extremely Rigid

Omnipredicativity in Classical Nahuatl

Classical Nahuatl, an Uto-Aztecan language spoken in Mexico and adjacent areas at the time of the conquest of America by Spain, is claimed to be a language whose content words are all mapped onto predicates (Launey, 1994). Thus, its lexical inventory of content words consists exclusively of verbs.

In classical Nahuatl morphology, the person markers for intransitive arguments (S) and for agents (A) are identical to the person markers for predicative constructions with lexemes that denote physical objects (cf **Table 4**).

Thus, the prefix *ni-* '1SG' can mark an action-denoting lexeme (*ni-chōca* [1SG-cry] 'I cry') as well as an object-denoting lexeme (*ni-ticitl* [1SG-doctor] 'I am a doctor'). Since the prefix for 3SG is zero, a seemingly simple sentence like (7) that would be translated as 'The child cries' can be analyzed as consisting of two predications: 's/he cries' and 'it is a child':

7. Launey (1994, p. 29):
   ϕ-chōca in ϕ-piltōntli.
   3.SG-cry LK 3.SG-child
   'S/he cries – it is a child'

Similarly, a transitive clause is expressed by three predications:

8. Launey (1994, p. 37):
   ϕ-qui-cua in ϕ-piltōntli in ϕ-nacatl.
   3.SG.A-3.SG.P-eat LK 3.SG-child LK 3.SG-meat
   'S/he eats it – it is a child – it is meat' for 'The child eats meat.'

The word *in* (glossed as LK for 'linker'; cf Launey, 1994, pp. 122–132) is generally used as a demonstrative or as a relative-clause marker. In its function as a linker (LK), both of these functions are used simultaneously. It is the demonstrative argument of one predication and the relative marker of the other. In (7), it is a demonstrative that takes the argument position of 'cry' (*ϕ-chōca* 'That one/he/she cries') and the relative marker of the second predication 'be a child' (*in ϕ-piltōntli* 'the one who is a child'). Thus, (7) may be translated literally as 'That one cries, the one who is a child.'

This analysis consistently accounts for person marking across action-denoting and object-denoting lexemes. It also integrates the functions of *in* as a demonstrative and as a relative-clause marker that produces cleft-like

Table 4 Person agreement markers on action-denoting lexemes and on object-denoting lexemes

	Action-denoting lexemes			*Object-denoting lexemes*	
	S/A	*P*	*Reflexive*	*S*	*Possessive*
1.SG	*n(i)-*	*-nēch-*	*-n(o)-*	*n(i)-*	*-n(o)-*
2-SG	*t(i)/x(i)-*	*-mitz-*	*-m(o)-*	*t(i)-*	*-m(o)-*
3.SG	*ϕ-*	*-c-/-qu(i)-*	*-m(o)-*	*ϕ-*	*-i-*
1.PL	*t(i)-*	*-tēch-*	*-t(o)-*	*t(i)-*	*-t(o)-*
2.PL	*aM-/x(i)-*	*-amēch-*	*-m(o)-*	*aM-*	*-am(o)-*
3.PL	*ϕ-*	*-quiM-*	*-m(o)-*	*ϕ-*	*-iM*

Adapted from Launey, M., 1994. Une grammaire omniprédicative. Essai sur la morphosyntaxe du nahuatl classique. CNRS Éditions, Paris, 10–11.

constructions. Because of free word order in classical Nahuatl, clefting can be used for marking information structure.

Tagalog and the Parts-of-Speech Hierarchy

A simple declarative clause in Tagalog starts with an action-denoting lexeme. What is crucial for the discussion of parts of speech is that this lexeme is marked for the semantic role of the constituent that is marked by the particle *ang*. Other categories marked on the first lexeme are aspect and kind of action (indicative, distributive, aptative, etc.). In (9a), the infix *-um-* of the action-denoting lexeme *bili* 'buy' marks the element *lalaki* 'man' in the *ang*-phrase as agent (A). The element in the *ang*-phrase has often been described under the terms of 'focus' or 'topic,' a terminology that is misleading, since *ang* rather functions as a marker of specificity (Himmelmann, 1997, p. 103). To avoid this problem, Schachter (1993) has introduced the term 'trigger.' The example in (9a) thus illustrates the function of agent trigger (AT). In (9b), the ϕ-suffix stands for patient trigger (PT). Thus, the element in the *ang*-phrase is marked as the patient on the clause-initial predicate (*b<in>ili-ϕ*). In addition to the roles of agent and patient, the predicate can also be marked for locative (locative trigger, LT) as in (9c) and for other roles like instrumental and benefactive. The elements that are not in the trigger function are introduced by other particles, among them *ng* for agents, patients, and some instrumentals and *sa* for locatives.

9. Tagalog (Foley and Van Valin, 1984, p. 135):
   a. B<um>ili **ang lalaki** ng isda sa tindahan.
      PFV:/AT/-buy T man P/A fish LOC store
      'The man bought fish at the store.'
   b. B<in>ili-ø ng lalaki **ang isda** sa tindahan.
      /PFV/-buy-PT P/A man T fish LOC store
      'The man bought *the fish* at the store.'
   c. B<in>il-han ng lalaki ng isda **ang tindahan.**
      /PFV/-buy-LT P/A man P/A fish T store
      'The man bought fish *at the store.*'

As was shown by Himmelmann (1987), trigger morphology can be analyzed as a certain type of morphological derivation that determines the orientation of a nominalized action to a participant with its specific semantic role. Thus, *b<um>ili* in (9a) can be analyzed as a nominal with agent orientation (cf English 'buyer'). Analogously, *b<in>ili-ϕ* in (9b) corresponds to 'the object that is bought' and *b<in>il-han* in (9c) to 'the place of buying.' In such an analysis, the clause-initial position has the function of a nominal predicate that is followed by the subject marked by the trigger *ang* (on subjects in Tagalog, cf Kroeger, 1993). Thus, the declarative construction as a whole takes the function of an equational construction.

This analysis is further supported by the marker *ng*, which is also used as a marker of possession:

10. lapis ng bata
    pencil POSS child
    'the pencil of the child'

With this background, example (9a) can be analyzed as 'The man is a buyer of fish at the store.' Similarly, (9c) corresponds to 'the store is the buying place for fish of the man,' etc. If this analysis is correct, all the slots in the equational constructions discussed in (9) are nouns. Thus, Tagalog can be described as a language whose constructional inventory is characterized exclusively by reference-related structures. From such a perspective, one may think of describing Tagalog as an extremely rigid language in terms of Hengeveld (2013; cf type 7 in **Table 3**). The problem with this analysis is that Tagalog only consists of nouns, a fact which falsifies the parts-of-speech hierarchy in (5).

Contentives: The Case of Tongan

Tongan (Austronesian: Central-Eastern Malayo-Polynesian: Oceanic: Polynesian) is described as a language whose lexicon does not preclassify content words for syntactic categories. Irrespective of their semantic class (object, action, property) and their morphology, lexical items of Tongan can occur in the verbal slot characterized by tense marking and in the nominal slot characterized by an article. Thus, the action-denoting lexeme *lele* 'run' takes the V-slot in (11a) and the N-slot in (11b). Similarly, the object-denoting lexeme *fefine* 'woman' is in the nominal position in (11a) and in the verbal position in (11b). Notice that Tongan is a verb-initial language:

11. Tongan (Broschart, 1997, p. 134):
    a. na'e **lele** e kau **fefiné.**
       PST run ART PL.HUM woman
       'The women were running.'
    b. na'e **fefine** kotoa e kau **lelé.**
       PST woman all ART PL.HUM run
       'The ones running were all female.'

This example differs from (6) inasmuch as the meaning of the lexemes can be predicted from their position. The lexeme *fefine* in (11b) means 'to be a woman/women,' while the lexeme *lele* means 'the one(s) who run(s)' (the diacritics on the clause-final words in (11) mark clause-final accents). Thus, Croft's (1991, 2000, 2001) argument against the analysis of Tongan as a highly flexible language in terms of Hengeveld (1992, 2013) does not work with (11). The fact that there may be a certain percentage of lexemes which show unpredictable semantic differences in different syntact functions as in (6) is not an argument against the overall analysis of a language as highly flexible. A limited number of instances of lexical specification as a separate process of lexicalization is always to be expected (cf Bisang, 2013 on classical Chinese).

Evans and Osada (2005) in their paper on Mundari (Dravidian) discuss three criteria that claims of the lack of noun/verb distinction must meet. Since they concentrate on the contentive type, their paper will be discussed here. Compositionality is the first criterion. Differences in meaning of the individual lexemes must be fully derivable from the meaning of the syntactic slots in which they occur. It seems to hold for most lexical items of Tongan but there are exceptions (cf example (6)) and it holds for classical Chinese (Bisang, 2008). Bidirectionality requires that if an object-denoting lexeme can take the V-position, an action-denoting lexeme

should also be able to occur in the N-position. As can be seen from (11), this condition is met. Finally, the lack of noun/verb distinction must hold for all the relevant words of the lexicon (exhaustiveness; cf my above remark on the acceptability of a limited number of exceptions).

On the Role of Morphology

Even though the noun/verb distinction is irrelevant for the lexicon/syntax mapping in extremely rigid languages like classical Nahuatl and Tagalog and contentive languages like Tongan, this distinction remains important at the level of morphology in each of these three languages. In none of them, the noun/verb distinction is obsolete.

In *classical Nahuatl*, the noun/verb distinction shows up in tense/aspect marking and in the number of arguments (Launey, 1994, p. 201). Quite a few tense-aspect markers only occur with action-denoting (and property-denoting) lexemes (e.g., *-z* for future, *-c* for perfective, *ō* for completed action, etc.; Launey, 1994, p. 28). The differences in terms of argument structure can be seen from **Table 4**. Object-denoting lexemes differ with regard to their relational structure from action-denoting lexemes. Object-denoting lexemes have only one relation (S-argument) plus a possessor argument (last column of **Table 4**), while lexemes denoting transitive actions have an additional secondary argument (P in **Table 4**). Finally, there are a considerable number of morphemes which are clearly associated with nouns. The most prominent marker which occurs exclusively with object-denoting lexemes is *-tl/-tli* [*-ɬ/-ɬi*] (Launey, 1994, p. 207–208).

In Tagalog, the noun/verb distinction can be seen from the compatibility with trigger morphology. Object-denoting lexemes like *lalaki* 'man,' *bata* 'child,' and *isda* 'fish' (cf (9)) cannot take trigger morphology, while action-denoting (and property-denoting) words like *bili* 'buy' can (Himmelmann, 2008). Thus, one can conclude that Tagalog is a language with distinct morpholexical categories but no distinct terminal syntactic categories that are associated with the syntactic slots for nouns and verbs.

In Tongan, there are lexical 'paradigms' (Broschart, 1997, p. 143) in the sense of sets of lexemes that can be combined with certain morphemes but these paradigms cannot be used for mapping into syntax. The morpheme *-Canga* (marker of domain) can be suffixed to action-denoting lexemes (*pule* 'govern' –> *pule'anga* 'government'), to property-denoting lexemes (*motu'a* 'old' –> *motu'a'anga* 'reason for having aged'), and to object denoting lexemes (*api* 'home' –> *apit'anga* 'homestead'). In spite of the nominal properties of these words, they can also take the verbal position characterized by its TAM marking.

Conclusion

The definition of parts of speech depends on four prerequisites (Criteria for Defining Parts of Speech section). Croft's (1991, 2000, 2001) approach only includes semantics, pragmatics, and form (Croft (1991, 2000, 2001) section), while Hengeveld's (1992, 2013) approach also includes lexicon/syntax mapping (Functional Grammar (Hengeveld, 1992, 2013) section). The discussion of some language-specific and typologically remarkable cases can only be understood if the fourth prerequisite of lexicon/syntax mapping is included (cf classical Nahuatl, Tagalog, and Tongan in the Short Case Studies and Problems section). From such a perspective, Hengeveld's approach is more comprehensive.

Both approaches offer typological generalizations. Croft's conceptual space for parts of speech (**Table 1**) offers a universal framework for the cross-linguistic comparison of parts-of-speech systems. Since this conceptual space does not include lexicon/syntax mapping, it cannot distinguish extremely rigid systems (type 7) from contentive systems. Hengeveld's parts-of-speech hierarchy in (5) can fully integrate this distinction but it may be empirically falsified by Tagalog (Tagalog and the Parts-Of-Speech Hierarchy section), a language with an extremely rigid parts-of-speech system that is based exclusively on nouns and reference-related structures. Hengeveld's approach additionally offers interesting claims of universal correlations between the seven parts-of-speech types and other grammatical domains of language (Functional Grammar (Hengeveld, 1992, 2013) section). To what extent they hold needs to be seen. At least the generalization that contentive-type languages should be either verb-initial or verb-final (Functional Grammar (Hengeveld, 1992, 2013) section) is problematic from the perspective of classical Chinese, which is a precategorial language with SVO word order.

Croft's and Hengeveld's approaches are the most thorough accounts of parts of speech from a universal perspective. A look at individual languages and the discussions on their parts-of-speech systems by specialists reveals that there still are some problems that require more research and theoretical thinking. What is interesting is the fact that the noun/verb distinction shows up in the morphological properties even of those languages which are sometimes claimed to have no noun/verb distinction from the perspective of lexicon/syntax mapping (cf the On the Role of Morphology section).

Party Identification and Nonpartisanship

Russell J Dalton, Center for the Study of Democracy, University of California, Irvine, Irvine, CA, USA

This article is a revision of the previous edition article by D. Sanders, volume 16, pp. 11099–11103, © 2001, Elsevier Ltd.

Abstract

Party identification (PID) is defined as an early-socialized, enduring, affective, psychological identification with a specific political party. It was detected by some of the first empirical studies of electoral choice in the United States. PID receives such importance because it can structure a person's view of the political world, provide cues for judging the candidates and issues of the day, shape voting choice, influence patterns of political participation, and promote stability in voting behavior. One can arguably claim that PID is the most important concept in modern electoral behavior research.

Origin and Evolution of the Concept

Angus Campbell and his colleagues (1960) based at the University of Michigan directed the first American national election surveys in the 1950s. As they examined how voters made their choices during an election, they noted that many people entered the campaign with their decision already made. Often people attributed their votes to long-standing family traditions, or values they had held across many elections. These partisan loyalties appeared to be a central part of individual belief systems, serving as a source of political cues for other attitudes and behaviors. The Michigan researchers described these partisan attachments as a sense of *party identification* (PID): a long-term, affective, psychological identification with one's preferred political party. Social identity theory argues that these partisan ties are similar to identifications with a social class, religious denomination, or other social group. Party attachments are distinct from voting preferences, which explains why some Americans vote for the presidential candidate of one party while expressing loyalty to another party. Indeed, the conceptual independence of voting and PID gives the latter its significance. PID emerged as a central element in these researchers' sociopsychological model of electoral behavior.

After the discovery of party ID in the United States, the concept was exported to other democracies where the Michigan scholars helped to establish new electoral surveys. In several cases, researchers had problems finding an equivalent measure of partisanship in multiparty systems or in nations where the term 'partisanship' holds different connotations for the voters. In Britain, for example, partisan loyalties run deep, and with a single parliamentary vote there are not the ticket-splitting choices that separate long-term loyalties from short-term vote choices as in the United States. In addition, the concept of a partisan 'independent' is not as common in other nations as it is in the United States, so there might not be a neutral nonpartisan category for people who did not feel close to any party. Researchers could not simply translate the American party ID question into French or German; they had to find a functional equivalent for measuring partisan attachments.

For nearly a decade in the 1970s and early 1980s researchers debated whether PID was a distinctly American phenomenon. Different surveys experimented with ways to ask about partisanship, and tracked the stability of measures over time. Eventually most election experts agreed that voters in established democracies hold some form of party allegiances that endure over time and shape their views of politics. These identities strongly influence perceptions of parties and electoral politics, judgments about the government of the day, and affect patterns of political participation.

How Partisanship Develops

Partisanship is similar to other personal identities; it reflects early life learning and the social conditions of the individual. Studies of young children found that many develop basic partisan ties at a very early age, often during the primary school years. Children learn party loyalties before they can understand what the party labels stand for – a process similar to the development of many other social identities such as religion or class. These early party attachments provide a reference structure for future political learning (which often reinforces early partisan biases).

In established democracies, parents play a central role in the socialization of these values. Research that compares the party identifications of parents and their children routinely finds high levels of partisan agreement in stable party systems. Parents successfully transmit their partisanship to their children because party loyalties are formed when parents are the dominant influence in a child's life. Parents commonly expose their children to partisan cues since political discussion frequently includes some partisan content. Consequently, it does not take long for a child to figure out his or her parents' partisan leanings from their reactions to television news and statements in family discussions.

Similarly, the parents' social situation provides politically relevant cues on what party is supported by others in one's church, social class, ethnicity, or region. Adolescents and young adults see which party their friends and coworkers support, which often reinforce their initial party ties. Thus, party identities become enmeshed in a web of other social identities that tend to persist through life. As a result, studies routinely find that party ties tend to strengthen with age – or more precisely with continued experience in supporting one's

early preferred party. For example, the 2012 American National Election Study reported that 48% of Americans under age 30 had a party identification, compared to 60% among those over age 60. The same age pattern appears in most established democracies.

The situation is different in many of the new democracies that have emerged as part of the democratization wave that began in the late 1980s and early 1990s. In these nations, such as the new democracies of Central-Eastern Europe, East Asia, and Africa, the democratic experience is new to parents and their children. Indeed, parents might struggle to adapt to the change in political regimes. Consequently, party ties lack the element of family and social traditions that reinforce these identities in established democracies. Parents cannot socialize partisan values that they lack themselves. The political parties running in elections are also new, and changes in the partisan lineup over time are likely. Research on partisanship in new democracies suggests that party ties will initially be weak, and will be learned slowly over subsequent elections if the party system stabilizes and families and social groups develop firm party loyalties. Thus, new democracies may require a generation or more to develop to levels of partisanship observed in established democracies.

Levels of Partisanship

One of the contentious issues involving partisanship is how to measure these orientations. PID means a long-term psychological attachment to a political party. To tap into these identities, the Michigan team developed what is now the standard question assessing PID in the United States:

> Generally speaking, do you think of yourself as a Republican, a Democrat, an Independent, or what?

If the respondents say they are a Republican or a Democrat, they are asked if they would call themselves strong (Republican/Democrat) or not very strong (Republican/Democrat). If they say they are independent, they are asked if they think of themselves as closer to the Republican or to the Democratic Party. American researchers use this question to create a seven-point party ID scale running from being a strong Democrat at one end, an independent close to neither party in the middle, and a strong Republican at the other end.

Cross-national research found that this question could not be used in some party systems because specific elements of the American question did not capture partisanship in multiparty parliamentary systems. After much debate, researchers developed questions to tap these allegiances that reflect national traditions and party system conventions. The now standard question on partisanship in Germany illustrates one nation's alternative:

> Many people in the Federal Republic lean toward a particular party for a long time, although they may occasionally vote for a different party. How about you: Do you in general lean toward a particular party? Which one?

This is an example of a functional equivalent to the American question even though the wording is different to reflect conditions in another nation. Other nations adopted their own measure (or alternative measures) of partisanship. Questions on PID are now asked in the election studies of virtually all contemporary democracies. There are predictable variations in the strength of these identities across nations, especially as a function of the longevity of the party system and the characteristics of the party system. In most nations, many people approach a new election with a predisposition toward a favored party already in place.

Because of these variations in political context and the phrasing of the partisanship question, it is complicated to compare levels of partisan cross-nationally. The best evidence on the extent of partisanship in a nation comes from the respective national election studies that ask a question suited to national conditions. But this is little help in comparing levels of partisanship cross-nationally if each nation uses a differently worded question. So instead we turn to the 2012 European Social Survey that asked an alternative party attachment question in about two dozen European democracies:

> Is there a particular political party you feel closer to than all the other parties? Which party is that? How close do you feel to this party? Do you feel that you are very close, quite close, not close, or not at all close?

This question exchanges the idea of a long-term partisan identity for the concept of closeness to a party. Closeness should produce a 'softer' measure of partisanship, which might make it easier to express a party attachment asked separately from immediate vote choice. Another advantage is that this question has been asked in recent surveys in the United States.

Figure 1 displays the percentage saying they are close to any party across several European nations and the United States. There is considerable variation in the level of partisanship across nations, ranging from about two-thirds in Denmark, Sweden, and Norway to less than a third in the nations at the bottom of the figure. Some of this cross-national variation might come from the inevitable differences in how a standard question is translated into each language or the specific events occurring in the nation. Overall, multiple waves of the European Election Survey find patterns similar to the evidence presented here.

Partisanship in the United States ranks above the European average. Given the past emphasis on the strong partisanship of Europeans, especially in proportional representation parliamentary systems, this is somewhat surprising. However, it may reflect the greater functional value of partisanship in the United States because of the long ballots and multiple choices that voters face. A Briton who casts 5–6 votes in a 5-year electoral cycle may feel less need to psychologically identify with a party than an American partisan who casts more than a hundred votes for local, state, and federal offices over this same period.

The other notable feature of the figure is the contrast between established democracies and the new democracies in Central-Eastern Europe. Four of the five nations with the lowest percentage feeling close to a particular party are from the East. Ireland is the only Western democracy in this group, and its low

Figure 1 Close to a particular political party. Sources: European Social Survey 2012; the U.S. results are from the 2008 American National Election Studies.

level of partisanship probably reflects a popular backlash against parties because of the economic collapse in 2009. Conversely, only one of the 10 nations with the highest level of party closeness is from the East. All else being equal, one might expect party ties to slowly grow in these new democracies as party choices stabilize, voting experience grows, and people develop a record of repeatedly voting for a preferred party. But even two decades after democratization, this East–West gap is still substantial.

Consequences of Partisanship

Politics can be a complicated undertaking for citizens; it takes considerable time and effort to follow the details of elections, the policy choices offered by the parties, and the veracity of campaign pronouncements. Especially in a parliamentary system with a large number of parties, making a decision can be a daunting task. PID first gained prominence as a method to simplify this process, to provide a cue or heuristic to guide political behavior. PID helps to make politics 'user friendly.' When the political parties take clear and consistent policy positions, the party label provides an information shortcut on how 'people like me' should decide. Once voters decide which party generally represents their interests, this single piece of information can act as a perceptual screen – guiding how they view events, issues, and candidates. A policy advocated by one's party is more likely to meet with favor than one advocated by another party.

Compared to social group cues such as class and religion, PID is a more valuable heuristic. Party cues are relevant to a broader range of phenomena because parties are so central to democratic politics. Issues and events frequently are presented to the public in partisan terms, as the parties take positions on the issues of the day or react to the statements of other political actors. People vote for parties or party candidates at elections. Governments are managed by partisan teams. So, reliance on partisanship may be the ultimate example of the satisficing model of politics.

There are many examples of how people use partisan cues to fill in voids in their political knowledge. For instance, if they are unfamiliar with a specific public policy, knowing which party favors or opposes the policy is a strong cue on what position to take. Similarly, party ties shape evaluations of new political candidates, because their party generally signals a broad political philosophy. Party cues also shape one's evaluations of the past and expectations for the future. When one's party wins office, for example, its partisan supporters are more likely to improve their predictions about the nation's political and economic future – even before the new government is installed. Many voters view politics through this perceptual screen.

Party ties also mobilize people to become politically active. Just like loyalty to a sports team, attachment to a political party encourages an individual to become active in the political process to support his or her side. The 2012 American National Election Studies found that turnout was 26% higher among strong partisans than among independents. In addition, strong partisans are more likely to try to influence others, to display campaign materials, to attend a rally, or to give money to a candidate during the campaign. Partisanship functions in a similar way in other established democracies. Strong partisans voted at a higher rate in the 2009 German Bundestag elections, and they were several times more likely to participate in campaign events and twice as likely to try to persuade others how to vote. Similar patterns exist for most established democracies.

Party identifications also structure voting choices. Partisanship means that a voter has a predisposition to support his or her preferred party. Partisanship has been described as the basis for a 'normal vote' – the vote expected when other factors in the election are evenly balanced. If other factors come into play, such as issue positions or candidate images, their influence can be measured by the change in preferences from initial partisan predispositions. For the unsophisticated voter, a long-term partisan loyalty and repeated experience with one's preferred party provides a clear and low-cost cue for voting. Even for the sophisticated citizen, a candidate's party affiliation normally signifies a policy program that serves as the basis for reasonable electoral choice.

Generally, there is often a very close relationship between PID and voting in parliamentary elections. In the 2010 British House of Commons elections, for example, 84% of partisans voted for their own party. The small number of elected offices in most established democracies and the party-centered nature of parliamentary campaigns tend to narrow the separation between partisanship and vote.

The American citizen, in contrast, has to cope with a vast number of candidates seeking a variety of offices at federal, state, and local levels. This encourages Americans to become conscious of a generalized tie to one party. The separation between attitudes and behavior is therefore the most noticeable in American elections, especially when voters are asked to make serial choices for local, state, and federal offices. In highly visible and politicized presidential elections, candidate images and issue appeals have the potential to counteract partisan preferences. The success of Republican presidential candidates from Ronald Reagan to George W. Bush, for example, occurred because they attracted defectors from the Democratic majority as well as independents. Similarly, the two-candidate runoff in French presidential elections is decided by the size of the vote the candidates can attract from parties other than their own.

At the national level, strong partisan ties can be a stabilizing influence on electoral politics. If most people identify with one of the established parties, then this lessens the potential for voters to be attracted to new parties or demagogic leaders. More generally, widespread partisan ties dampen the impact of short-term political events on election outcomes and limit the potential electoral appeal of new political personalities. Extensive partisanship among the electorate thus works to stabilize party alignments and lessen electoral change.

In summary, partisanship is the ultimate heuristic because it

- creates a basis of political identity
- provides cues for evaluating political events, candidates, and issues
- mobilizes participation in campaigns and election turnout
- provides cues on voting preferences, and
- stabilizes voting patterns for the individual and the party system

Research Controversies

Because PID is so central to understanding citizen political behavior, there is continuing research on the nature of partisanship and its correlates. One of the most visible research controversies focuses on potential changes in the levels of partisanship. American election studies noted a decline in the percentage of party identifiers starting in the mid-1960s. With some variability, this trend has continued to the present. Where once only a quarter of Americans lacked a party identity, in 2012 roughly 40% were independents; this means nonpartisans are a plurality compared to either Republican or Democratic identifiers.

Eventually, similar declines in partisanship became apparent for other established democracies in Europe, North America, and the Pacific Rim. Long-term election studies for these nations broadly show a shrinking number of partisans or a weakening of the strength of party identities. There are parallel declines in the number of people who are members of a political party, and favorable opinions of political parties have broadly declined. These patterns provide evidence for what Dalton (2012) describes as *partisan dealignment* – a persisting decline in the public's level of partisanship.

If partisanship structures the political behavior of average citizen, as many experts argue, then the broad cross-national evidence of dealignment over the last several decades may be a cause of concern. Significantly fewer people now approach politics with a fixed party loyalty – although many people do still have party allegiances. When a plurality of citizens lacks party identities, this has the potential to reshape electoral behavior and the nature of citizen politics.

Several electoral experts have questioned the existence of these trends in the United States and other democracies. The most common criticism in the United States is that many people claim to be nonpartisans because it is fashionable to be independent, but then they actually behave like hidden partisans. Other research demonstrated that partisans in the United States remain loyal voters, so the overall impact of party ID on vote choice has changed only slightly. Similar doubts were raised about the dealignment trends in European democracies. The centrality of partisanship is so great that many scholars doubted that these ties were really weakening.

With additional evidence across time and across nations, the evidence of dealignment has mounted. It is not a phenomena linked to the political history of any one nation, such as a rejection of American political parties because of the issue controversies or scandals of the past several decades. Moreover, there are behavioral manifestations of weakening party ties. For example, there is cross-national evidence that fewer voters enter elections with standing party preferences that endure to Election Day, and more voters are deciding later in the campaign based on the events of the election. With weaker party ties, turnout in elections has also generally declined in established democracies. Other research indicates that contemporary publics are more likely to shift their party preferences between elections, because fewer have firm party loyalties. Thus, the volatility in electoral results has increased. And since party ties systemically stabilize party systems, the erosion of party ties has been accompanied by the emergence of new political parties of all colors that can capture these floating voters. Because of its sources in the changing nature of contemporary societies and citizen values, dealignment is likely to be a continuing feature of electoral politics in established democracies.

This evidence of dealignment stimulated concerns about the consequences for electoral politics and democracy overall. Previous studies had found that nonpartisans were largely disengaged from politics, ill-informed on the issues of the day, and seldom voted. More citizens like this would not benefit the democratic process. However, the rise of nonpartisans is disproportionately concentrated the young and better educated, who follow politics and participate despite lacking party loyalties. Thus the growth in nonpartisans has the potential to increase the number of voters who more closely follow the theoretical model of an informed, rational voter.

Much of the dealignment literature focuses on established democracies, attributing these trends to broad forces of social and political change – such as changing norms of citizenship, increased education, and a more assertive media. But similar forces are at work in many emerging democracies. There is some evidence that partisanship is not developing in many new democracies, as prior theorizing would predict. Instead, citizens are hesitant to develop party allegiances, and some elites react by stressing personality over party. While established democracies are undergoing dealignment, many new

democracies are failing to develop party alignments in the first place, which has generated research on this irregular learning process and its consequences.

Another research controversy focuses on whether PID actually fits the assumptions of the initial sociopsychological model of electoral behavior. The original formulation of partisanship defined it as an affective psychological identity, which implied it would show relatively high stability through the life span and structure perceptions of the political world to generate this persistence. In contrast, Fiorina's (1981) rational choice approach suggests that partisanship can be treated as a 'running total' of accumulated partisan experience. Or in Bayesian terms, individuals may begin with a prior partisanship based on early life socialization, but then this partisanship is constantly updated by successive experience. If one voter supports his preferred party in an election, then his party ID might strengthen. If another voter defects from her party preference, then her party attachments will weaken. This is a much more dynamic view of partisanship.

The rational choice approach was a positive step forward in understanding partisanship, but it is not an either/or choice. Repeated interviews with the same people demonstrate that partisanship is one of the most stable of political attitudes, more resistant to change than major economic or cultural policy positions. Yet party ties do sometimes change. The issue is the relative balance between stability and change, the force needed to produce lasting change in partisan loyalties, and how this varies across different population subgroups. For individual citizens, the stable element of party identity is typically stronger than the forces for change. Thus, changes in party vote shares between elections often come from nonpartisans or new voters who lack strong partisan loyalties.

A more recent critique by Lavine et al. (2012) questions the value of PID as a heuristic for making informed democratic choices. They argue that partisanship might not just color political views, but may act as blinders that shield partisans from discordant information that is necessary for making informed choices. If friends of my friends are always friends, and friends of my enemies are always enemies, then partisans are unlikely to see alternatives for discourse and compromise – and the making of better choices. Indeed, other scholars have stressed the vulnerability of heuristics as a basis of informed democratic choice. Even if it is right most of the time, blind heuristics cannot identify when the wrong choice is being presented. This is especially problematic when citizens have limited political sophistication to make informed choices without partisan cues.

In summary, research clearly suggests that if one wanted to understand the political behavior of individuals with a single question in a survey, then PID would be the best question to ask. It provides a conceptual framework for many citizens, shaping their views of politics, and their political activities. Thus even if levels of partisanship are dropping as a result of dealignment, partisanship provides the touchstone for understanding political behavior. After reviewing four decades of electoral research on partisanship, Weisberg and Greene (2003) concluded "Party identification is the linchpin of our modern understanding of electoral democracy, and it is likely to retain that crucial theoretical position."

Abstract

A party system is the system of interactions between political parties that results from their mutual competition or cooperation. For party systems to exist there must therefore be more than one party involved. Beyond the requirement for a plurality of parties, party systems can be said to exist only when these interactions between the parties are patterned, familiar, and reasonably predictable. A plurality of parties is therefore a necessary but not sufficient condition for the existence of a party system. When it comes to the classification of party systems, the most common and traditional approach is based simply on the number of parties in competition, usually distinguishing between two-party systems, on the one hand, and multiparty systems, on the other. Greater insight is offered by the more elaborate classification developed by Sartori, which takes into account not only the number of parties, but also the ideological distance that separates them. The core of all party systems, and their most defining feature, involves the structuring of competition for executive office. Party systems as systems are strongest and are most institutionalized when this structure of competition is closed. They are weakest, and more or less nonexistent, when it is wholly open.

A party system is the system of interactions between political parties that results from their mutual competition or cooperation (see Sartori, 1976, p. 44). For party systems to exist there must therefore be more than one party involved. One-party states do not have party systems. Beyond the requirement for a plurality of parties, party systems can be said to exist only when these interactions between the parties are patterned, familiar, and reasonably predictable. A plurality of parties is therefore a necessary but not sufficient condition for the existence of a party system. Parties that exist alongside one another, but that do not interact in any patterned or structured fashion, do not make for a party system as such.

While it may seem difficult to conceive of situations in which a plurality of parties exists without at the same time embodying a set of patterned interactions, two types of limiting cases can be identified. The first is where each of the parties involved exists in an entirely self-sufficient world, based on a closed electoral constituency, with neither its survival nor performance being in any way effected by the other parties in the polity. Even in this limiting case, however, the absence of interactions at the electoral level might well be accompanied by the need to interact – through competition or cooperation – at the parliamentary or governmental level. Thus, while no electoral party system would exist, it might well prove possible to speak of a party system in parliament. The second type of limiting case is where a new multiparty democracy is being established more or less from scratch, such as in the wake of a democratic transition, and where neither the new parties themselves, nor their interactions, have stabilized sufficiently to allow the identification of a distinct pattern. In these situations, a party system may be in the process of being structured or institutionalized but it cannot yet be said to have definitely emerged. In their survey of party systems in Latin America, Mainwaring and Scully (1995) adopt a similar distinction in specifying party systems as either 'institutionalized' or 'inchoate.' Strictly speaking, however, an inchoate or noninstitutionalized party system is a contradiction in terms: to be a system is to be institutionalized.

Classifying Party Systems

Although scholars have paid relatively scant attention to what defines a party system as such, tending instead to assume the existence of a party system in all polities where there exists a plurality of parties, they have devoted considerable effort to distinguishing between different types of party system. The most conventional and frequently adopted approach to distinguishing party systems is based simply on the number of parties in competition, and the most common distinction involved here, which goes back to Duverger (1954), is very straightforward – that between two-party systems, on the one hand, and multiparty (i.e., more than two) systems, on the other. This particular classification was also believed originally to reflect a more fundamental distinction between more or less stable and consensual democracies, such as the United Kingdom and the United States, which were seen as typical of the two-party variety, and more or less unstable or conflictual democracies, such as Fourth Republic France, Italy, or Weimar Germany, which were seen as typical of the multiparty type. Although this simple association of numerical categories of party system with levels of political stability and efficacy was later undermined by reference to a host of smaller democracies that were characterized by both a multiplicity of parties and a strong commitment to consensual government, the core distinction between two- and multi-party systems has continued to be widely employed within the literature on comparative politics, although it is sometimes modified by taking into account not only the sheer numbers of parties in competition, but also their relative size. Thus, Blondel (1968), for example, uses the relative size of the parties to distinguish four types of party system: two-party systems, two-and-a-half-party systems, multiparty systems with a dominant party, and multiparty systems without a dominant party.

The most substantial attempt to move away from a primary reliance on the simple numbers of parties in competition was that of Sartori (1976, pp. 117–323), who combined counting the parties with a measure of the ideological distance that

separated them. Sartori's typology was the first that focused directly on the interactions between the parties – the 'mechanics' of the system – and hence on the differential patterns of competition and cooperation. Following this approach, party systems could be classified according to the number of parties in the system, in which there was a distinction between systems with two parties, those with up to some five parties (limited pluralism) and those with some six parties or more (extreme pluralism); and according to the distance that separated the parties lying at either extreme of the ideological spectrum, which would either be small ('moderate') or large ('polarized'). These two criteria were not wholly independent of one another, however, in that Sartori also showed that the format of the system, that is, the number of parties, contained 'mechanical predispositions,' that is, it could help determine the ideological distance, such that extreme pluralism could lead to polarization. When combined, the two criteria resulted in three principal types of party system: two-party systems, characterized by a limited format and a small ideological distance (e.g., the UK); moderate pluralism, characterized by limited or extreme pluralism and a relatively small ideological distance (e.g., Denmark or the Netherlands); and polarized pluralism, characterized by extreme pluralism and a large ideological distance (e.g., Weimar Germany, early postwar Italy, or pre-Pinochet Chile). Sartori also noted the existence of a 'predominant-party system,' in which one particular party, such as, for example, the Congress party in India, or the old Unionist party in Northern Ireland, consistently won a winning majority of parliamentary seats.

Party Systems and Structures of Competition

At the core of any party system is the competition for executive office. It is this that structures the party system in the first place, and facilitates its institutionalization. Moreover, albeit often implicitly, the competition for executive office is also the most important criterion employed in many of the various classifications of party systems. Two-party systems, for example, are referred to as such not because there only two parties present themselves to the voters – indeed, this is rarely if ever the case – but rather because only two parties matter when it comes to forming a government, be this in a presidential or a parliamentary system. In two-and-a-half or multiparty systems, by contrast, there are more than two parties that enjoy the potential access to executive office. Even within the more complex classification developed by Sartori, it is the competition for office that proves most important. Sartori's moderate pluralism, for example, involves competition between alternative coalition governments, whereas polarized pluralism involves a patterns in which a center party or parties is more or less permanently in office, with one or more extreme parties being permanently excluded from government.

It follows from this that party systems might best be understood not only in terms of some all-embracing classification, within which the question of the numbers of parties in competition obviously plays an important role, but also in terms of contrasting patterns of government formation (Mair, 1997, pp. 199–223). Three related criteria are important here. The first concerns the ways in which governments alternate with one another, where systems in which there is a regular process of wholesale alternation, in which incumbents are replaced wholly by former nonincumbents, may be separated from those in which alternation is only partially complete. Systems in which two alternative parties or coalitions alternate with one another (the USA, the UK, Fifth Republic France) may therefore be distinguished from those in which one or more parties leaves office, while another remains, albeit often with a new coalition partner (Belgium, the Netherlands). The second, relevant criterion here is familiarity, where systems in which government is always contested by the same parties or sets of parties may be contrasted with those in which patterns of government formation prove more innovative or promiscuous. In postwar Ireland, for example, voters had long become accustomed to facing a choice at election time between, on the one side, the powerful *Fianna Fáil* party, which always governed alone, or, on the other side, a coalition of all of the smaller parties. Once *Fianna Fáil* decided to opt for a coalition strategy, however, in 1989, government formation became more innovative, and the formerly familiar patterns broke down. The third criterion involves the degree of access to the government formation process, and the extent to which new parties can hope to win a place in the executive. New parties have always found it relatively easy to join innovative government coalitions in the Netherlands, for example. In the UK, by contrast, no party other than the Conservatives or Labour has gained access to government since 1945.

Putting these three criteria together enables party systems to be ranged along a notional continuum according to the degree to which the structure of competition is open or closed. At one extreme lie the wholly closed systems, such as the UK or the US, where alternation in government is always wholesale, where government formation processes are wholly familiar, and where new or third parties are always excluded. At the other extreme, it is difficult to speak of a party system at all: there is no discernible pattern in how governments alternate, the potential alternatives themselves are unfamiliar and may never have governed before, and access to office is, in principle, open to all. To travel from this latter extreme to the other is therefore to witness the progressive closure of the structure of competition, which is simply another way of saying that systemness itself increases. Party systems as systems are strongest and are most institutionalized when the structure of competition is closed. They are weakest, and more or less nonexistent, when this structure is wholly open.

To understand party systems in this way, and hence to treat the systemness of a party system, or its degree of institutionalization, as a variable, also affords an insight into the question of the persistence and change of party systems. Strongly institutionalized party systems will inevitably enjoy a bias towards persistence, not least because the parties at the core of such systems will have a vested interest in maintaining the existing structure of competition. It is for this reason, for example, that Lipset and Rokkan (1967) could speak of the 'freezing' of west European party systems in the wake of full democratization in the 1920s. Less institutionalized systems, on the other hand, will prove more susceptible to change. This approach also affords an insight into the relationship between party systems and individual parties, for it is not just the individual parties that together create the party system, but also the party system

that acts to reinforce the role and standing of the parties themselves.

Abstract

This article gives an overview about a decade of passion research (2003–2013). First, definitions and measurements of passion are introduced, differentiating between general models on the one hand and domain-specific definitions on the other hand. Second, the relations of passion to other constructs are addressed and the research findings concerning similar constructs, predictors, correlates, and outcomes of passion are summarized. Finally, open research questions and directions for future research are discussed.

Introduction

Some individuals persist in activities such as playing the piano or doing research over a long time, and some of them practice these activities continuously and intensely despite occurring obstacles, frustrations, and other aversive experiences (Ericsson et al., 1993). Yet, many of the individuals report being passionate about the respective activity and desire to engage and persist in their effortful practice (Bonneville-Roussy et al., 2011). It is known that persistent practice is needed during the process of becoming an expert (Ericsson et al., 1993), but little is known about the motivation that keeps some individuals on track while others drop out. One explanation for such motivation to persist in effortful activities is the construct passion. This article introduces definitions of passion and describes how passion has been measured, reviews existing research approaches and findings, and finally discusses open questions that should direct future research on passion.

Defining and Measuring Passion

There are many different definitions and measures of passion. The term passion has different connotations in everyday life, different cultures and disciplines and its connotations have changed much across the centuries (Dixon, 2003). Therefore it is complicated to reach a clear, consensual, and scientific definition of passion. Even within psychology, there is no consensual concept but a variety of passion definitions. Many authors use the term implicitly, presupposing that readers understand the meaning without further explication. This has led to terminological ambiguities: Everybody understands what passion means, but different people understand different things. Implicit definitions often use passion as a synonym to strong interest (e.g., Achter and Lubinski, 2005; Pressley et al., 1992; Gagné, 2007), consistently pursued interests (Duckworth et al., 2007), and strong and persistent motivation in learning and achievement contexts (e.g., Achter and Lubinski, 2005; Mills, 2003; Moraes et al., 2004; Noble et al., 2008; Wai et al., 2009). In addition, several explicit psychological passion definitions were proposed (Cardon et al., 2009b; Fredricks et al., 2010; Renzulli et al., 2006; Vallerand et al., 2003). Most explicit definitions include intense, mostly positive emotions, approach motivation, and long-term commitment as passion components. Some describe general aspects of passion (Fredricks et al., 2010), while others refer to specific types or components, or contexts of passion (Vallerand et al., 2003), some conceptualize passion as a hedonic experience (Vallerand et al., 2003; Fredricks et al., 2010), while others emphasize more the experience of approach motivation. The core characteristics of the different explicit passion definitions are described below.

Domain-Unspecific Models of Passion

The Dual Model of Passion: Harmonious versus Obsessive Passion

Very influential is the dual model of passion (Vallerand et al., 2003). The authors define passion as "a strong inclination toward an activity that people like, that they find important, and in which they invest time and energy" (Vallerand et al., 2003, p. 756). According to the dual model, passionate individuals identify with the activity. Different forms of identification supposedly cause two different types of passion. The adaptive harmonious passion (HP) describes the identification with an autonomously chosen activity, whereas the maladaptive obsessive passion (OP) describes the compulsion to engage in an activity that results from intra- or interpersonal pressure.

The dual model of passion has been studied with self-report questionnaires among individuals from child age to high-age adults, in different countries and languages, and in many different contexts and activities (e.g., sports, music, dance, political engagement, work contexts, teaching, and gambling; for an overview see Marsh et al., 2013). Vallerand et al. (2003) measure three aspects of passion: general passion criteria, HP, and OP. The general passion criteria (liking, finding important, investing time and energy, and labeling oneself as being passionate) were used in some studies to

distinguish between passionate and nonpassionate individuals (e.g., Bonneville-Roussy et al., 2011; Philippe et al., 2009b; Rip et al., 2012). The authors asked individuals about an activity, which they intensively practiced (play of music instruments, political engagement, and the individuals' favorite activity) and categorized individuals as passionate if they obtained above-scale midpoint scores on the mean-composite of the above-mentioned passion criteria. According to this cutoff, the vast majority of the investigated individuals was categorized as 'passionate' for the corresponding activity. HP and OP are strongly correlated with the general passion criteria, and the correlation between HP and OP ranges from low (e.g., Marsh et al., 2013) over moderate (e.g., Rip et al., 2006; Vallerand et al., 2007) to high (e.g., Séguin-Lévesque et al., 2003; Vallerand et al., 2006, 2003, 2008b). Most studies concerning the dual model of passion investigated differences between HP and OP. In contrast, differences between generally passionate and nonpassionate individuals are rarely investigated in these studies.

The Com.pass Model: Passion as Coincidence of Commitment and Desire

A definition of specific components of general passion was suggested by Moeller and Grassinger (2014a) as a result of a review and integration of the previous research on passion and commitment. In their commitment and passion (com.pass) model, the authors define passion as a coincidence of desire and commitment, where desire is defined as affect-intense approach motivation and commitment as motivation to persist, according to the investment model of commitment (Rusbult et al., 1998) and the related sport commitment model (Scanlan et al., 2009). In line with these models, commitment is subdivided into the subcomponents 'continuous intent to engage and persist,' 'long-term goals,' and 'identification with the activity.' These three components of commitment and the fourth passion component 'desire' can be measured with a self-report questionnaire developed by Moeller and Grassinger (2014b). These passion components and their relations to measures of commitment, personality traits, and other constructs have been investigated in samples of adolescents and young across different activity contexts (including soccer, poker, and dance) and in different countries and languages.

The com.pass model differs from the dual model of passion in its emphasis on the general degree rather than types of passion and its distinction between specific components of general passion. Furthermore, the com.pass model does not distinguish between HP and OP. A particularity is moreover the integration of the previously separated research lines on passion and commitment within the com.pass model, and the findings that established passion and commitment scales both measure the same construct. In contrast to the dual model of passion (Vallerand et al., 2003), the com.pass model defines the experience of affect-intense approach motivation ('wanting') as an essential component of passion.

Passion as Intrinsic, Self-Relevant Absorption

In contrast to the previously described approaches, Fredricks et al. (2010) used qualitative interview data from a long-term longitudinal study to identify passionate individuals. The authors investigated passion among (1) adolescents who were perceived by themselves, their teachers, and parents as 'talented' for extracurricular activities such as, e.g., dance, instrumental music, sports, or drama and (2) adolescents who were identified as 'gifted' by their elementary schools and belonged to the 25% highest performing students among the gifted students. These students had been high performing and intensely engaged in these respective activities for years and were interviewed about a variety of themes including their experiences and aspirations in the activities they were intensely engaged in. The authors defined adolescents to be passionate if they (1) reported that they wanted to do the activity all the time, (2) got intense involvement in the activity and experienced emotional release through the activity, (3) invested much time and energy into doing the activity, and (4) identified with the activity. Fredricks and colleagues found that passion was a rare, exceptional experience, eventually reported by some individuals with intense engagement in extracurricular activities, but virtually never by individuals high performing and intensely engaged in academic activities.

Fredricks and colleagues' definition of passion resembles the above-described definitions of the dual model and the com.pass model in its description of a person–activity relationship and its inclusion of desire, commitment, and self-relevance as characteristics of passion. The main differences to other passion definitions are the applied qualitative measurement instrument, the finding that passion in terms of the authors' criteria was a rare, exceptional phenomenon, and the authors' definition of involvement and absorption as essential components rather than just correlates of passion.

Domain-Specific Models of Passion

Passion as Part of the Triangular Theory of Love

A domain-specific definition of passion was suggested by Sternberg (1986), who described passion as one of three love components in his triangular theory of love. He defined passion as a short-term sexual attraction of one person to another, including intense longing for the other person, frequent thoughts about the other person, and arousal (Sternberg, 1997). This definition differs from the above described in the understanding of passion as a quickly fading state, distinct from commitment, and in its reference to persons (or objects, see Albert et al., 2008) instead of activities as objects of passion. A corresponding measure is the passion subscale of the triangular love scale (Sternberg, 1997, p. 329). Sternberg's passion concept influenced the research about love in romantic relationships (e.g., Azevedo and Aron, 2009) and the research about a consumer's love for brands and products (e.g., Albert et al., 2008), but it has not been applied in the research on passion for activities.

Entrepreneurial Passion

Entrepreneurial passion is another domain-specific concept, defined as "consciously accessible, intense positive feelings experienced by engagement in entrepreneurial activities associated with roles that are meaningful and salient to the self-identity of the entrepreneur" (Cardon et al., 2009b). This definition resulted from a thorough review of commonalities

and differences of different passion concepts in the entrepreneurship literature. The authors distinguish between different entrepreneurial activities and link them to three different role-identities and corresponding types of entrepreneurial passion: (1) the inventor identity, (2) the founder identity, and (3) the developer identity. There are two different instruments for the assessment of entrepreneurial passion: a self-report questionnaire with subscales assessing passion for inventing, founding, and developing (Cardon, 2008; Chen et al., 2009; Cardon et al., 2009a), and an instrument to assess how the entrepreneurial passion of one person is perceived by others, distinguishing affective, cognitive, and behavioral aspects of entrepreneurial passion (Cardon et al., 2009a). The instruments are described as reliable and valid by the authors, but detailed reports about their psychometric properties have not been published to date. Cardon (2008) states that her context-specific measures of entrepreneurial passion are important innovations and cannot be substituted by the dual-model passion scale (Vallerand et al., 2003) applied to entrepreneurial activities, because an empirical comparison of these measures showed that they assess different phenomena.

Relations of Passion to Other Constructs

The relation of passion to other experiences and behaviors is addressed in many studies (e.g., Fredricks et al., 2010; Vallerand et al., 2003). Several motivational constructs overlap with passion in some aspects, which can create confusion and redundancies. In order to remedy terminological ambiguities, we therefore map similarities and differences between passion and related constructs in the following, and then summarize the existing research about the predictors, correlates, and outcomes of passion below.

Theoretical Mappings of Overlapping Constructs

Fredricks et al. (2010) provided the first systematic comparison between passion and similar, overlapping constructs. According to the authors, passion includes the experience flow, which is an exceptional and rewarding state of intense absorption, concentration, and loss of self- and time-monitoring (Csikszentmihalyi, 1996). Furthermore, Fredricks et al. (2010) described similarities between the passion-component identification with an activity, and the concept of attainment value, i.e., the subjective importance to perform well on a given task because of its relation to the individuals' self-concept (see Wigfield and Eccles, 1992).

Another overlapping construct is the 'well-developed personal interest' (Hidi and Renninger, 2006). Passion and personal interest describe pleasant experiences, whose content is well known and valued by the individual, and in which the individual desires to persist. Another overlapping is Winners' (1996, 2000) construct 'rage to master.' This construct and Fredrick et al.'s notion of passion both describe intrinsic and obsessive motivation to acquire skills in a given domain and include experiences of obsessive interest, loss of interest for the 'outside world,' and the sharp focus on the area of expertise. One of the most similar concepts to passion is commitment, which shares all of its components with passion (see above). Commitment is a part of passion, according to the com.pass model, and the other above-mentioned constructs are partially similar but distinct. In sum, passion is a multifaceted construct that overlaps in some of its components with other constructs. The discriminant and incremental validity of passion over these overlapping constructs is understudied at the moment this article was written.

Predictors of Passion

Several empirical studies have investigated the predictors of passion, most of them focusing on differential predictors for HP and OP in terms of Vallerand et al. (2003). According to the dual model of passion, HP is supposedly predicted by autonomous identification with an activity, whereas controlled identification with an activity is supposed to predict OP. This was supported by Mageau et al.'s (2009) findings that parental autonomy supports positively predicted HP, whereas parental activity valuation predicted OP. Similarly, Bonneville-Roussy et al. (2013) found that musical students' perception of getting autonomy support by their teacher predicted HP, whereas the perception of being controlled by the teacher predicted OP, while identification with playing music predicted both types of passion. Similar findings were reported by Vallerand et al. (2008a), who found that an autonomous personality orientation predicted HP, a controlled personality orientation predicted OP, and activity valuation predicted both. Concerning the predictors of the general degree of passion, Mageau et al. (2009) found that children's identification with the activity, their preference to specialize in that activity, and the autonomy support provided to them by their parents predicted the development of general passion for music 5 months later.

Several studies have tried to disentangle person-specific and activity- or situation-specific preconditions of passion (e.g., Amiot et al., 2006; Balon et al., 2013; Rip et al., 2012). Most authors conceptualize passion as a relationship of a person toward an activity and assume that the degree of passionate individual experiences is determined by both personal- and situational-specific characteristics and their interactions. A simultaneous study of both person-specific stable and situation-specific fluid components of passion was reported by Moeller et al. (under review), who found in a longitudinal Experience Sampling Approach that situational determinants accounted for 80% of variance in passion, whereas about 20% of the variance was due to person-specific determinants. Particularly, specific facets of extraversion (dispositional approach motivation and positive trait affect) are related to several passion measures (Moeller et al., 2014). Moreover, several studies on links between HP and OP and the big five personality traits found small and inconsistent correlations (Balon et al., 2013; Tosun and Lajunen, 2009; Wang and Yang, 2008).

Regarding activity-specific preconditions, Fredricks et al. (2010) found that extracurricular activities are far more often experienced in a passionate way than academic activities. Concerning the interaction of personal- and activity-specific characteristics, Amiot et al. (2006) found that an interaction between the type of passion and the competitiveness of the team sport predicted the psychological adjustment of elite hockey players. Obsessively passionate individuals were better

adjusted in highly competitive teams, whereas in less competitive teams the harmoniously passionate individuals were better adjusted.

Correlates of HP and OP

Many studies investigated correlations of HP and OP with other constructs. HP is positively correlated with intrinsic experiences and adaptive behavior, such as, e.g., flow (Philippe et al. 2009a; Vallerand et al., 2003; Carpentier et al., 2012), psychological and physical well-being (Vallerand, 2012; Vallerand et al., 2006), deliberate practice (Bonneville-Roussy et al., 2011), positive affect during and after activity engagement (Philippe et al., 2010), and maintained control over the activity (Vallerand et al., 2003; Mageau et al., 2005). In contrast, OP is correlated with maladaptive and undesirable experiences such as loss of control and symptoms of dependency (Ratelle et al., 2004; Philippe and Vallerand, 2007), negative affect during activity engagement and when the individual is prevented from doing the activity (Philippe et al., 2010; Vallerand et al., 2003), sport injuries (Rip et al., 2006), ruminative thoughts about the activity (Carpentier et al., 2012), aggression under identity threat (Rip et al., 2012), impaired concentration (Ratelle et al., 2004), problematic persistence (Vallerand et al., 2003), and relationship conflicts (Séguin-Lévesque et al., 2003).

Outcomes

There are huge expectations regarding the outcomes of passion. Passion is expected to make "life worth living" (Marsh et al., 2013; Vallerand et al., 2003, p. 757; Vallerand, 2008) and to increase well-being, positive affect, and motivation in general (Fredricks et al., 2010). HP is expected to cause desirable outcomes such as high achievement (Bonneville-Roussy et al., 2011), whereas OP is supposed to cause problematic behavior and suffering. In a short-term longitudinal study, Bonneville-Roussy et al. (2011) found that HP predicted mastery goals, deliberate practice, and performance in musical instrument play, whereas OP predicted performance approach and avoidance goals and predicted lower performance (for similar findings see Vallerand et al., 2007, 2008a). In contrast, Bélanger et al. (2013) found in experimental studies that OP predicted greater performance in the condition in which the individuals received the information that they had failed in a previous task, whereas HP was unrelated to the information about success or failure.

Directions for Future Research

Many questions remain unanswered to be investigated in future research. In their literature review about entrepreneurial passion, Cardon et al. (2009b) identified the following important desiderata and research gaps that are equally relevant for the general research about passion: (1) how (entrepreneurial) passion can be defined clearly and theoretically based, (2) whether (entrepreneurial) passion could be understood as a personality trait or rather an activity- or situation-specific experience, and (3) which conceptual model could explain the influence of (entrepreneurial) passion on relevant outcomes. Additional specific questions are discussed below together with directions for future research.

Problems Regarding the Conceptualization of Passion

Need for Consensus about Definitions, Components, and Measures of Passion

The disparate definitions and measures of passion still contribute more confusion than insights to the psychology of motivation. First, reviews have tried to remedy the existing ambiguities by integrating similar definitions (e.g., Cardon et al., 2009b). However, most publications refer to only one definition and measure of passion but interpret their findings as valid insights about passion in general. In order to ensure that findings are interpretable and generalizable beyond the applied measure, we need more knowledge about the (in-)variance between different definitions and measurement instruments of passion. Open questions are, for instance: Which operationalization of general passion is more useful: a dichotomous or continuous variable? Which would be a useful cutoff score for dichotomous passion definitions? The currently applied cutoff at the scale midpoint (e.g., Bonneville-Roussy et al., 2011; Philippe et al., 2009b; Rip et al., 2012) seems arbitrary, so future research should determine better criteria for the distinction between passionate and nonpassionate individuals.

Person-Oriented Analyses: General Degree versus Specific Types of Passion

The psychological literature about passion has often stated assumptions about differences between harmoniously passionate and obsessively passionate individuals (e.g., Vallerand et al., 2003). In line with this assumption, numerous variable-centered studies have shown differences between the scales for HP and OP. However, the frequent assumption that individuals are either harmoniously or obsessively passionate has been challenged by findings of several cluster analytical studies, which did not find any group of predominantly harmoniously or obsessively passionate individuals, but instead groups of individuals with mainly high, or low, scores in all subscales of passion (Moeller et al., 2014; Wang and Yang, 2008). These findings together with the often moderate to high correlation between HP and OP (see above) raise the question whether HP and OP are different types in terms of homogeneous groups of individuals or rather aspects of passion that are measured by distinct scales but which can co-occur within individuals. A useful framework for corresponding future studies would be the distinction between variable- and person-oriented approaches (Bergman and Magnusson, 1997). If individuals shall be described properly, then it is probably more insightful to analyze the existence of homogeneous subgroups of individuals and the person-specific development (person-oriented approach), instead of the previous praxis to rely on analyses of (cor-) relations between variables across all individuals (variable-oriented approach).

The above-mentioned cluster analyses indicate that the general degree of passion accounts for group differences. Therefore, future studies should shed more light on the so far neglected difference between high and low passion.

Particular Functioning and Interactions of Specific Components

The explicit definitions of passion conceptualize passion as a multifaceted construct, but most studies do not address the particular functioning and interaction of these facets. Consequently, the contribution of the specific components to the explanation of the relevant outcomes of passion is unclear and should be studied more extensively. One of the strengths of the construct passion is its integration of short-term motivational intensity with aspects of long-term commitment, which is an important research desideratum (Katz, 1999; Duckworth et al., 2007). This potential to bridge previously separated research lines within a joined framework is lost if the mechanisms through which the different components influence the outcomes are not explained in testable models and empirical studies. The distinction between specific components of passion promises new insights, given that studies assessing specific facets (e.g., of personality) are generally more informative and better interpretable than those relying on higher order factors (Armstrong and Anthoney, 2009; Beauducel et al., 2007; Bipp et al., 2008; Schimmack et al., 2004).

The distinction between specific components could also remedy redundancies in relation to other constructs, because it is easier to identify overlaps and differences between two constructs if their specific components are comparably laid out.

The measurement model underlying integration of the specific components of passion to one composite score should be theoretically sound and empirically insightful. Current measures average and weight all passion components equally. For example, the passion-criteria score of the dual model of passion is computed as the mean score of the items that assess liking, finding important, spending time and energy, and declaring an activity to one's passion (Vallerand et al., 2003). However, the extent to which the different components contribute to the explanation of relevant criteria might be different, and this should be reflected in the applied measurement models. More research is needed to determine which measurement model best represents the specific functioning and interaction of the components and their specific contribution to the prediction of relevant outcomes.

State versus Trait Concepts of Passion: Related Problems

Need for Integrative Use of State and Trait Measures; Pleading for a Larger Variety of Research Methods and More Objective Measures

Several studies have addressed trait-aspects or situation-dependent aspects of passion separate of each other, but both approaches are rarely integrated in a joined study or model. In order to disentangle person- and situation-specific determinants of passion, future studies should apply trait and state measures together.

Most studies applied self-report assessments and situation-unspecific measures. Such measures are known to be prone to biases, because the individuals commit errors when they retrospectively remember, evaluate, and mentally aggregate their physical arousal across several situations (e.g., Goetz et al., 2013); moreover, some experiences like physical arousal are not necessarily consciously aware and therefore not validly reportable. Future studies should apply more objective and in-the-moment assessments of passion. Particularly, the strongly situation-dependent components like the affect intensity (emphasized, e.g., in the definition of Cardon et al., 2009b) could be more validly assessed with situation-specific measures such as the Experience Sampling Method or with psychophysiological assessment of arousal such as electrodermal resistance or pupil dilatation.

The validity of the trait measures could be enhanced by more objective measures such as reports by teachers, or peers, which would also help to find out how individual passion is perceived by significant others (Cardon et al., 2009a). A limitation of the previous research of person-specific determinants of passion is that most studies missed all those individuals who dropped out at earlier time points of the learning process before the highly engaged samples were assessed (e.g., Bonneville-Roussy et al., 2011). More representative samples and dropout analyses could help to understand why some individuals persist passionately, while others drop out of the respective activities.

Problems Related to the Aim to Explain Relevant Criteria

Incremental Validity

The previous research left unanswered whether passion contributes incrementally to the explanation of relevant phenomena. Incremental validity is proven when passion contributes additional explanation of the relevant criterion after *all* similar constructs are taken into account. Eventual findings of incremental validity of passion over one or two related constructs would be only one piece of the puzzle. If the incremental validity of passion could be shown, it would be interesting to know which specific components account for it and whether there is also incremental validity in the *prospective* prediction of relevant criteria by passion in comparison to other constructs.

Need for Process Models Explaining the Stability and Long-Term Development of Passion, Its Predictors, and Outcomes

Most authors conceptualize passion as a long-term stable experience (e.g., Vallerand et al., 2003; but see Sternberg, 1986, 1997). However, the stability of passion is rarely investigated. There also is a lack of theoretical models to explain how passion and its long-term predictors and outcomes develop. Furthermore, there is a lack of appropriate longitudinal studies on the development, predictors, and outcomes of passion. The existing studies are mostly cross-sectional. The few longitudinal studies do not sufficiently describe the long-term development of passion because most of them only investigated periods of few months (e.g., Amiot et al., 2006; Bonneville-Roussy et al., 2013; Mageau et al., 2009; Philippe et al., 2010; Vallerand et al., 2006, 2007, 2008b) and often did not assess whether passion *changed* in dependence of certain predictors, thus not allowing one to test the assumed causal effects of passion on its hypothesized outcomes.

Prospective longitudinal studies assessing the change in predictors, outcomes, and in passion itself are required in order to test assumptions about predictors of passion. For instance, a central assumption of the dual model of passion states that HP results from the autonomous internalization of an activity and OP from the controlled internalization (Vallerand et al.,

2003). However, very few studies assessed the *preceding* determinants of passion *before* the passion developed (e.g., Mageau et al., 2009; Vallerand et al., 2006), so it is not known conclusively to what extent the type of passion is determined by preceding forms of internalization. Further investigation is also needed in regard to the unknown long-term development of HP and OP.

Importantly, there is a need for testable models explaining the long-term development of passion, its predictors, and outcomes. The current research is inconsistent: In different studies the same construct (e.g., flow, meaning intense absorption and concentration on current tasks) figures as predictor of passion (Fredricks et al., 2010), correlate of passion (Vallerand et al., 2003), or essential component of passion (Fredricks et al., 2010). Possibly, iterative process models such as dynamic systems approaches (e.g., Lichtwarck-Aschoff et al., 2009) could explain how a construct such as flow can be both antecedent and result of an individual's passionate inclination toward an activity, and how such experiences can reinforce each other in iterative cycles. However, currently, there is no such theoretical model. The specification and empirical testing of process models is a task for future research to complete.

In sum, passion is a relatively new construct that has inspired a rapidly growing number of studies since the publication of the dual model of passion in the year 2013. Several different definitions were proposed. Most authors conceptualize passion as a multifaceted construct that describes the inclination of a person to engage in particular activities. It is often assumed that passion remains stable across long time periods and that passion explains long-term persistence in the corresponding activities. Trait and state components of passion were discussed here. Variable-oriented approaches have shown important differences between harmonious and obsessive subscales of passion, whereas cluster-analytic approaches showed that within individuals, HP and OP are mostly aligned, meaning either similarly high or low.

Pastoralism in Anthropology

John G Galaty, McGill University, Montreal, QC, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Pastoralism is a mode of subsistence that involves raising domestic animals in grassland environments using herd and household mobility. Combined with nomadism, pastoralism has allowed humans to inhabit the world's vast dry lands. Pastoral systems are adaptations to diverse political and ecological conditions, but today are influenced by national and global societies. Livestock are objects of pastoralist identification used for subsistence, market sale, social exchange, and symbolic expression and were the world's first currency. Against the tragedy of the commons argument, pastoral use of rangelands is sustainable, and should continue as pastoralists increasingly participate in global institutions and cultural modernity.

What Is Pastoralism?

Pastoralism is a mode of subsistence that involves raising domestic animals on natural pastures, a livelihood practice mainly pursued in dry grassland environments that support few competing forms of land use. Pastoralism requires herd and household mobility as herders continually seek fresh grazing. Indeed, the nomadic element has made possible successful human habitation of vast areas of the world's grasslands and semideserts using locally appropriate breeds: cattle, small stock, and dromedaries in Africa, dromedaries, sheep, and goats in the Middle East, camels, cattle, and sheep in Central Asia, yaks in mountainous areas of the Tibetan Plateau, llama and alpaca in the Andean highlands, and reindeer in the circumpolar Tundra. But the frequency of pastoral mobility increases as a function of the low level, unpredictability, and dispersed nature of rainfall received in various grassland regions. Pastoralism usually relies on family or community-based labor for animal care, achieving economies of scale when relatively few pastoralists herd large numbers of domestic stock across wide expanses of pasture, though sometimes herds are contracted out. It thus involves using labor intensively but land extensively, in contrast to intensive land use in mixed peasant farming or capital intensive ranching (Galaty and Johnson, 1990). As a livelihood strategy, pastoralism as an enterprise focuses mainly on milk production for family use, but also relies on domestic animals for meat and traction, to the end not of maximizing livestock numbers but of optimizing the human population supported in dry lands (Dyson-Hudson and Dyson-Hudson, 1980).

The theoretical concerns of the anthropology of pastoralism have changed over time, from querying how pastoralism fitted into evolutionary sequences, to asking what functions livestock play within an integrated cultural pattern, to exploring how the social institutions of pastoral societies relate to herding livelihoods, to investigating what type of society is characterized by nomadism and pastoral specialization, and how these societies work (Ingold, 1984). Today, it is recognized that all pastoral groups reflect the influences of national and global societies, while representing adaptations to particular political and ecological conditions. Key questions now concern how those with strong engagement with animal husbandry respond dynamically to climate change and environmental stresses, the spread of national and global institutions, challenges to their security of land holding, expansion of market relations, the growing influence of governments, their use of international law as indigenous peoples, and more diffuse processes of social change and modernization (Hodgson, 2011). A new anthropology of the contemporary does not render earlier questions irrelevant, but contextualize them within national and global trends and encroachments on pastoral autonomy.

The Many Functions of Livestock

Although many livestock-keeping peoples engage in numerous other productive activities, such as hunting, fishing, horticulture, arboriculture, and smuggling, still pastoralism looms large when practiced by entire societies. Such societies are often organized around sociopolitical institutions, beliefs, and practices that reflect pastoral preoccupations: political organizations given structure by territorial sections or localized clans, segmentary lineages or age-set systems, bodies of indigenous knowledge about livestock and range ecology, and symbolic practices that reflect the centrality of domestic animals and their husbandry. Livestock are both the 'products' that pastoralists produce (as live animals, milk, meat, skins, etc.) and the 'means' of production, since animals both beget products and more animals, used for subsistence and sale. Livestock also are used as stores of value, objects of investment, and units of exchange (i.e., 'money') in terms of which the value of other goods can be denominated (Schneider, 1979). Indeed, a 'head' (*caput*) of domestic animals represented the original form of financial 'capital' among the Romans. Exchange of domestic animals also serves as means of *social* reproduction, of marital ties via bride-wealth, networks of friendship through gifts, and solidarity among social groups through sacrifice. These social and economic functions underpin the intense personal and affective attachments herders feel toward domestic animals, as well the elaborated systems of classification and poetic and religious expression, and complex bodies of ethnozoological and ethnoecological knowledge that are

part of pastoralists' cultural endowment. Since pastoralists raise each animal from birth, their familiarity with individual stock is intensely personal, and on the basis of this intimacy people identify with and define themselves through their domestic animals.

Theories of Pastoralism

Morgan and after him Marx proposed, biblically, that pastoralism evolved from hunting and foraging economies, with stock representing the first forms of property. But the archaeology of southwestern Asia suggested that animal and plant domestication arose together, with protodomesticate animals attracted to grains found near human habitations. Pastoralism was a specialized form of husbandry that arose when herders and domestic stock moved into drier lands distant from cultivated fields. However, more recent studies show that the first cattle were likely domesticated around 9000–8000 BCE by wild grass-gathering and pottery-making Northern Sudanians profiting from the southern spread of *Bos taurus* into the Sahara during a wetter period, about a 1000 years before cattle were domesticated in the eastern Mediterranean and the Middle East and later in India (Ehret, 2002). So animal domestication may in fact have evolved out of hunting and grass gathering in northeastern Africa about a 1000 years before plants were domesticated in the same region.

The modern anthropological study of pastoralism was initiated with Herskovits' (1926) study of the 'cattle complex' in East Africa that described the cultural elaboration of livestock-centered ideas and practices but misguidedly suggested that domestic stock were objects of just religious rather than also economic value. Evans-Pritchard's (1940) pathbreaking studies of the Nuer of the Sudan emphasized the centrality of animal husbandry to Nuer subsistence, but also to understanding Nuer ecology and the territorial politics based on the segmentary lineage system, kinship, and religion. Scholarly effort was spent trying to typologize livestock keepers, as 'pure' or 'semi'-pastoralists, nomads and seminomads, belying the fact that diverse livestock keepers adopted different degrees of pastoral specialization and mobility according to changing conditions, and both produced and consumed agricultural produce as needed and as available. Detailed ethnographies of pastoral societies of Africa and the Middle East conceptualized and modeled pastoral systems from ecological, economic, and political perspectives.

The ecological approach asked to what extent pastoralism and forms of social organization represented adaptations to the distinct environments in which pastoralism is found. Certainly dry land environments influence the territorial systems that regulate herd mobility, but many key social and cultural institutions in pastoral societies reflect regional cultural patterns that cut across both sedentary and nomadic communities, and thus demand historical rather than ecological explanations. Careful analysis of dynamics of herd growth, the demographics of human fertility and mortality under constraints of pastoral nutrition and labor and the productive potential of various grassland regimes produced models of ecological balance between herd and human populations and pasture dynamics, the latter providing protein and caloric resources for humans through the mediation of ruminants (Dahl and Hjort, 1976; Homewood, 2008).

The economic perspective, which drew from formalist (classical), substantivist, and Marxian approaches, has examined the strategic decisions pastoralists make in the context of subsistence husbandry and market production of livestock and has theorized the linkage between the material processes of mobile husbandry and social and cultural systems. From the Marxian perspective, it was asked whether there was a distinctive 'pastoral mode of production' (most say 'no'), while from a classical economic view whether herders sought to 'maximize' herd sizes or to 'optimize' them in relation to herders' actual objectives of supporting human communities, human needs being traded off against herd growth through the division of milk between calves and children. Rather than utility maximizers, some proposed that pastoralists more closely resembles the domestic-based family firms of early capitalism, described by Weber, where hard work by all family members together with low personal consumption, savings, and reinvestment within a strict religious-based ethic, encouraged capital growth and economic expansion by tightly knit domestic units. In France, scholars contributing to the development of Marxian theory in Anthropology insisted that the technical practices of dry land husbandry could not explain pastoral social and ideological systems, since institutions and ideologies themselves serve as historical determinants of the social relations of production that shape how material practices unfold (Lefébure, 1979). Everywhere today, even remote pastoral communities have been incorporated into a broad system of capitalist relations, reflected in market networks and new forms of authority, though 'articulated' with precapitalist or customary social practices, ideologies, and economic orientations.

The political perspective, inspired by the work of Evans-Pritchard and Frederick Barth, proposed that pastoral political systems were not only shaped by the exigencies of animal husbandry but also by power relations that related herders to a hierarchy of authority within their own groups, to pastoral and sedentary neighbors with whom they interacted, competed, and conflicted, and to states, which persistently sought to pacify, capture, or 'encapsulate' nomadic pastoralists within their own structures of authority and control, including the right of taxation. Nomadism came to be seen not simply as ecological but also political adaptations, aimed at avoiding and evading state control, since centralized authorities could exert less control over peoples who are able to exercise the 'exit' option (Salzman, 2004). While pastoralists were able to exercise bristly autonomy, they interacted judiciously with their neighbors through multilingual trade, exchange and often intermarriage, both defending ethnic boundaries and flexibly sliding across lines of identity. Indeed, while some pastoralist individuals and families exercise ethnic fluidity, some entire groups moved into cultural and ethnic boundary areas where cultural and linguistic practices were exchanged and shared, with the essential identities of some groups evolving over time (Schlee, 1989). The binding together of pastoral polities, such as the Maasai, depended not just on leadership or centralizing forms of organization but shared languages, cultural exchanges, and rituals and emergent forms of identity (Spear and Waller, 1993).

Pastoralism: A Type of Society or a Continuum?

The notion that pastoralism is an adaptive livelihood strategy leads us to ask whether pastoralism is a 'type' of society or economy, or rather a vantage point for understanding how livestock husbandry affects livelihoods, regional relationships, and cultural commitments of communities that are in fact quite diverse. Pastoralists primarily use domestic livestock for subsistence, market sale, and social exchange, while agropastoralists use them for traction, transport, and manure, to support the agricultural economy, secondarily for subsistence. Where the money economy is weak, because currency is unavailable in remote, rural areas or too fungible among networks of kin and neighbors, investments from agriculture into livestock, or vice versa, may be viable household strategies for accumulating capital. Pastoral households usually hold more than one head of cattle per person, often much more, while agropastoralists usually possess less, so the value of livestock among agropastoralists may be higher than among pastoralists, due to proportionate weight of animals in small versus large herds. The social and ritual value of livestock, especially cattle, may be quite high in both systems. But agropastoralists must dedicate relatively large amounts of labor to herding small numbers of livestock along the margins of fields, so fail to enjoy the efficiencies of scale that pastoralists profit from, where a boy or man alone can manage a herd of 50–100 beasts or more grazing across an expanse of grasslands. Should we consider as pastoralists only those who specialize in extensive, mobile animal husbandry, or any who endow livestock with significant social, economic, symbolic, and ritual weight, independent of whether they are also engaged in cultivation, hunting, fishing, market sales, or other pursuits in a complex economy? The 'pastoral continuum' stretches from deserts to well-watered lands, where agriculture is also viable, from highly mobile to sedentary husbandry, from highly specialized to highly diversified systems, with animal husbandry, crop production, hunting, foraging, fishing, and trade combined within a single domestic economy (Spencer, 1998). Some largely produced for subsistence (e.g., the Baluch, Karamojong, Nuer), while others were strongly market-oriented (e.g., the Basseri and Bedouin), and over time change has occurred in what is being produced (e.g., The Bedouin of the Arabian peninsula have switched from camels to sheep, northern Samburu from cattle to dromedaries, Inner Mongolians to goats for cashmere) and by what means (Bedouin adopting trucks!).

What Comes First: Commitments of Herders or Needs of Animals?

Though most pastoral systems value a particular predominant species (witness the 'cattle culture' in East Africa), most pastoralists keep a complex of domestic animal species. Since domestic species thrive in different microenvironments, find different grasses palatable, need water on varying schedules, and can cover different amounts of terrain in a herding day, pastoralists are often faced with decisions about whether to herd species together by compromising on how well their various needs are fulfilled or splitting the herd into smaller management units by species. The Turkana of East Africa, for instance, may keep all domestic species together in the rainy season, but as the dry season progresses keep the camels and goats together in the lowlands, and the cattle and sheep together in the highlands, and in severe drought keep each species separate. As a result, families may cooperate among themselves in providing labor for herding subgroups, or a family may divide its members among several sub-homesteads pursuing specialized herding (McCabe, 2004). Family labor allocation may be made even more complicated if cultivation is considered, since some members may move to prepare fields in the late dry season, while herds circulate between sparse pastures and dwindling water resources. Across a region controlled by the same pastoral group, such as the Somali, drier areas are primarily used by dromedaries, less dry areas for small stock and cattle, resulting in certain subgroups being associated with different species mixes. Do pastoralists with commitments to certain valued livestock seek out the most suitable environmental niches for those species, or do they adopt the species that are most adapted to the environments they come to politically control? Fulani historically have traversed Africa from west to east along the savanna corridor compatible with their cattle and small-stock herding, and camel keepers from Central Asia have migrated throughout the cold arid zone where Bactrian camels thrive, but Oromo speakers migrating into drier regions in the Horn of Africa have adopted dromedaries as the most adaptable animal for the drier ecozones they have come to inhabit (Schlee, 1989). History, culture, and ecology all influence the shape of pastoral systems.

From Studying Pastoralism to Studying Pastoralists

During the last 25 years, the study of pastoralism has extended from the integrated perspective of Anthropology to more specialized studies in the social and natural sciences; at the same time, Anthropology has assimilated questions and approaches from diverse other disciplines, from Economics and Development Studies to Geography and Range and Animal Sciences. Focus has moved from theorizing pastoral systems as such to the analysis of emergent conditions that affect livestock keepers and grassland societies, including ecology and climate change, property rights and land fragmentation, the spread of livestock markets, state-directed programs of development, international conservation, and the spread of global institutions, like schools, clinics, churches, and vehicles. Further advances have been made in the three founding areas mentioned earlier, of pastoral ecology, economics, and politics. Light has also been shed on other problems that currents of social change in pastoral and rangeland communities have stimulated.

Current Perspectives on Pastoralism and the Environment

A significant influence on thinking about how grazing interacts with dry land environments stemmed from an article by Garret Hardin (1968) called 'The Tragedy of the Commons,' which used the desire to put one more head of cattle on a piece of commonly held pastures as a metaphor for how any resource

without designated owners, from which benefits could be realized without concomitant costs, would in principle be overused. Without reference to empirical work on institutions that do regulate use of common pool resources (Ensminger, 1992), the tragedy of the commons argument held that pasture degradation could only be avoided if common holdings were transformed into either private or state property, policy prescriptions for land reform that guided, and still guide, the design of rangeland development programs. With the aim of studying human–livestock–environmental interactions, the South Turkana Ecosystem Project pursued long-term interdisciplinary research with the highly mobile Ngisonyoka Turkana of northwestern Kenya, with collaboration among anthropologists, ecologists, nutritionists, and range scientists. Analyses of pastoralist mobility demonstrated how household labor could be mobilized to carry out multiple strategic moves involved splitting and recombining of households and herds in order to respond to microclimatic conditions and momentary grazing opportunities. Ecological study, led by James Ellis, revealed that the long-term empirical effects of grazing pressure on pasture quality under 'non-equilibrium conditions' were in fact minimal, since the grassland vegetation systems – having evolved over millennia in which rainfall was low, unreliable, and unpredictable – rejuvenated after rainfall (Galvin et al., 2008).

The theoretical and policy implications of these findings are great, since the 'density independence' of many rangeland ecosystems essentially vindicated the major principles of pastoral land use, which involved building up herds in good seasons to optimally exploit standing pastures, while accepting herd die-downs in times of deprivation, and using rapid and opportunistic herd movement both to access areas where pastures were replenished and to relieve the pressure that is exerted on local pastures under conditions of sedentarization or herd fixity (Scoones, 1994). In short, rather than customary pastoral range use practices being seen as the source of long-term rangeland degradation, they were seen as adaptive in the face of intrinsic constraints on maintaining herds and human populations in the dry lands, and to reflect sound understanding of range dynamics, which required herd mobility to 'track' temporally unpredictable and spatially dispersed grazing resources (Homewood, 2008). In the work of Bollig (2006), pastoral institutions were viewed as mechanisms for avoiding or mitigating the risks inherent to dry land husbandry, whether avoiding risks of pasture exhaustion through herd movement, the protection of grazing and livestock through territorial political systems, the spreading of risk through livestock exchange and building social networks, or the forging of age-set organization to ensure rapid response to threats to territories. Rather than aiming to achieve static 'equilibrium' between livestock and pastures, difficult under conditions that constantly varied, the approach to rangeland 'complexity' emphasizes the importance of 'resilience' of land use practices and pastoral husbandry in response to dramatic variations in ecological and political conditions.

Pastoralism within Regional Economies

The evolving understanding of how pastoral economies work was also influenced by the tragedy of the commons argument, in its view that perverse economic motives led pastoralists to pursue herd growth without considering its effect on rangeland ecologies. The misunderstanding that pastoralists sought herd growth for reasons of 'prestige' or religious value only (associated with Herskovits but still repeated by development theorists) exacerbated misperceptions regarding pastoral range degradation. Careful study of domestic pastoral livestock production strategies focused on the multiple functions of domestic stock, the careful optimizing of milk allocation both for family subsistence and calf nourishment, and strategies of allocating pasture labor to best care for herds in the context of accessing pasture, water, and mineral resources. McPeak and Little (2006) studied the judicious use of livestock markets in Eastern Africa, demonstrating the high degree of market integration of pastoral producers and their important contribution to the regional food and export economy. The transnational flow of livestock from pastoral areas feeds great capital cities and provides significant exports, which should vindicate pastoralists against the charge that they are not contributing to national economies. The cash needs of households have grown as pastoralists participate in complex national and global institutions, including schools, clinics, trade in clothing, tools and foodstuffs, and commodities that support animal husbandry, including veterinary drugs (Catley et al., 2013). Two common herding strategies involve moving the community along with herds or moving herds out from a settled community, the latter facilitating agropastoral pursuits. As pointed out by Barth (1961), both rich and poor pastoralists tend to settle, but, whether sedentarized or not, pastoral groups are increasingly diversifying their sources of household revenues, whether through the buying and selling of livestock at market, cultivation where possible, business or professions for the more highly educated and relatively wealthy, and wage labor and trade for the less wealthy and poorer. Diversification for some households is a poverty response as their herds diminish, but for other households it is a strategy for growth built on the base of animal husbandry. One outcome of economic stratification in both West and East Africa is the increasing investment in livestock by members of the urban elite, whether or not of pastoralist origin, who become absentee herd owners with stock tended by hired herders (Little, 1992). In the work of Homewood and collaborators, Maasai livelihood diversification is seen as an enlargement of economic opportunities within a complex economy, not a turning away from animal production (Homewood et al., 2009). For some, wildlife conservation offers opportunities for cash incomes from land leasing and tourism, but these revenues tend to be captured by local elites rather than being shared among pastoral communities.

The Politics of Pastoralism in National and Global Systems

Increasingly the Middle Eastern and Central Asian political model of nomadic herders integrated in complex relations with states and markets (Khazanov, 1984), the latter providing crucial food supplements and supplies on which husbandry depends, seems applicable to sub-Saharan Africa. In this regard, markets are an arm of government, responsible for

pulling pastoralists toward sites where they access social services and trade and participate in national and international exchanges of goods, information, and identities. Orbits of pastoral movement take into account the need to access towns to find social and political security, so semisedentarized homesteads are often established near towns where children can attend schools and everyone can access town life, most importantly health services and retail markets (Fratkin et al., 1994). Yet the centripetal force of sedentarization is constantly countered by the centrifugal force of pastoral movement to access pastures; in the context of semisedentarization near town, livestock are often moved by young men to more distant grazing, thus dividing the community between semipermanent settlements and mobile camps. The pattern of increasingly large settlements out of which livestock herds are moved to access distant grazing is replicated across the dry lands in response to insecurity and modernization, leaving some areas less intensively occupied but opening up opportunities for more diversified occupations in growing small towns that relieve environmental pressures that might otherwise be exerted by growing populations.

Though pastoralists are often characterized by urban dwellers in pejorative terms that associate them with their rural proclivities, as 'conservative,' resistant to change, traditionalists, and so on, they increasingly participate in globalized institutions, attending schools, accessing modern medicine, using markets, discussing national politics, tuning into radio and even television programs, and using mobile phones, the latter used to share information on available pastures and market prices, not to mention planning of gatherings, ceremonies, and martial pursuits. The social cohesion of many pastoral groups, involving strongly defended social boundaries, has in many instances been bolstered by resilient forms of local religion, involving shared beliefs and ritual practices. Schlee points out that to be a Borana or a Gabra was long associated with a refusal to embrace Islam. Yet increasingly pastoralists reflect a larger trend toward conversion to one of the world's great religions, notably Islam or Christianity, the result of which is to link often remote societies to much larger communities of belief, assuring them of participation in the globalized world. Though conversion is often more of a collective than an individual experience, a political choice, as it were, it often reflects deep discord within pastoral societies, between those who convert and those who resist conversion, the educated and noneducated, and those who vehemently affirm customary practices – not least important being those related to gender expectations – and those who call for change. Pastoral societies are increasingly socially diversified so resist singular characterizations.

The Land Factor

Rangeland Enclosures and Global Land Grabbing

In many areas, the most significant intervention of the state into rangeland affairs has been through the pursuit of 'pastoral development' carried out by means of land reforms that have sought to formalize pastoral land tenure, allocating identifiable lands to certain pastoral groups and over time to individuals. In some countries like Botswana, land reform has resulted in a pastoral elite gaining legal authority over vast lands via the 'borehole syndicates' described by Peters (1994), relegating small herders and hunters to proletarian status. Many early attempts in Niger, Tanzania, and Kenya to create formal pastoral groups with land rights over specified herding territories were largely unsuccessful, both because of the near impossibility of restricting grazing to defined territories under conditions of low and unpredictable rainfall and the difficulty of managing internal transactions in the absence of customary precedents for coordinating husbandry between hundreds of households managing thousands of livestock across dry land terrain (Sandford, 1983). Important studies of rangeland privatization demonstrate not that collectively held pastures lead to the 'tragedy of the commons' but that breaking trust when some individual 'enclose' and 'privatize' collectively held land initiates the 'tragedy of the enclosure,' as individuals inexorably seek their own piece of land, no matter how nonviable, if they fear a 'run' on the commons that might leave them with nothing (Galaty, 1994). Increasingly smaller units of land holding have been progressively demarcated among the Maasai of Kenya throughout the twentieth century, dividing pastoral commons into the Masai Reserve, into two and then three districts, into pastoral 'sections,' then Group Ranches, and finally individual family parcels under title deeds (Rutten, 1992). Maasai rangeland privatization has encouraged marginal agricultural practices, land speculation, and land sales, as land buyers often seek title deeds to use as collateral more than land itself, leading to land loss by herders, to the benefit of rural and urban elites and investors.

Socialist land reforms in the developing world often involved forced sedentarization and consolidation of pastoralists in formally constituted 'villages.' Despite economic liberalization many postsocialist governments claim radical title to all land, making pastoralists subject to arbitrary displacements when their land is appropriated for mining, wildlife conservation, or allocation to national or international commercial enterprises (Shivji, 1998). Given the alienation of mobile livestock keepers from government, leaders often view grasslands as unoccupied or used inefficiently, so ripe for allocating to outside investors (Galaty, 2013a). The Ethiopian government, for example, argues that its land lease policy makes otherwise unused lands available to multinational agribusinesses, but in fact it is engaged in what international observers call 'land grabbing' in the most fertile regions occupied by pastoralists, the 'wetlands in the drylands,' along the Awash River of the Afar, or the Omo River Valley, long the home of diverse Omotic, Sudanic, and Eastern Cushitic speaking pastoralists, such as the Dassanetch, Mursi, Bodi, and Arbore. Elsewhere, pastoralists engaged in community conservation and ethnotourism, often near National Parks, Game Reserves, or Conservation Areas such as Ngorongoro, find themselves elbowed aside by national elites or by tourist entrepreneurs allocated local lands by national governments. In the name of economic globalization, investors being allocated lands for commercial exploitation ignore property rights that in their own countries would require agreements with local landholders. In China, Tibetan, and Mongolian herders are being forcibly moved off their grazing lands under the principle of 'ecological resettlement,' a policy that

uses environmental degradation as a pretext for appropriating pastoral lands for both political and economic reasons. What seems clear is that claims by postsocialist governments to radical title to all national lands is a stratagem for depriving rangeland pastoralists, among others, of the lands that they require for animal husbandry or alternative uses emerging with livelihood diversification and social change. What national elites call 'development' is too often purchased with poverty for many pastoralists, among other rural dwellers.

Borders and Conflicts: How Pastoralists Resist the State

The state has become the strongest force controlling pastoral polities, and the imposition of national borders is one crucial mechanism in its doing so. Most national borders that cross dry lands (and the logic of national integrity most often puts wet and fertile regions at the center, low drylands at the borderlands!) slice across pastoral territories, dividing herding communities between contiguous countries. Especially in pastoral regions, this inconvenience disrupts social life and rational patterns of land use, since borders often divide markets from customers and sellers, dry season from wet season pastures, ritual sites from the ceremonial celebrators, and wife-givers from wife-takers. Pastoralists today do cross some borders with impunity, but are rarely unaware that they are doing so and as a result risk sanctions. But borders also afford opportunities and in this sense represent 'resources' that mobile people exploit (Feyisse and Hoehne, 2010). Pastoralists are some of the world's greatest black-market profiteers, moving goods back and forth between countries; Bedouin in Gaza and Sinai, Afar to and from Djibouti, Somalis into Kenya, are examples of pastoralists who have come to play major roles in regional economies, illicitly but profitably moving goods and guns acquired from distant producers to remote customers, as quintessential middle-men. They also move themselves between countries, acquiring multiple citizenships or identity cards, establishing credential as refugees in one place, while maintaining rights in sites of origin. In Moyale, between Kenya and Ethiopia, electoral competition draws ethnic compatriots from one country to tip the balance of voting in another (Fekadu, 2010).

Pastoral culture has long been associated with the potential for violence, because raiding and retaliating is intrinsic to an economy of valuable yet removable goods (i.e., domestic animals) in the absence of adequate political security, making the need to protect herds from predators and thieves culturally ingrained. Borders represent virtual curtains that hide raiding parties preparing to cross into a neighboring region, and a haven for thieves to retreat to after carrying out a successful foray. Alliances between contiguous cross-boundary segments of the same ethnic group provide resources for carrying out transborder transactions, but their occupying different nations can also begin to divide them into mutually hostile groups. Many insurgencies are carried out by pastoralists, often with the assistance of cross-border allies. The Tuareg insurgencies in Mali and Niger, the most recent associated with Islamist motives, have recurred throughout the twentieth century, and the Somali insurgencies, in Ethiopia, Kenya, Djibouti, as well as Somalia, have been so successful that they have completely eliminated the state! The now successful southern Sudan civil war for secession pitted southern pastoralists against the northern government, while the Darfur conflicts have seen pastoralists from Chad and northwest Sudan resist the formalization of tenure in highland areas that would prevent them from accessing seasonal pastures. The proposition that pastoralists are egalitarians because of their ethic of independence and mutual autonomy has some merit, but ignores that pastoral honor is often purchased at the price of the subjugation of other peoples in regional systems of stratification, whether among Bedouin or Baluch of the Middle-East or the many Saharan societies (Salzman, 2004).

Pastoral Futures

Is there a future for nomadic pastoralism? Constraints on the continuing practice of pastoralism include progressive land loss that diminishes the availability of pastures, pressures on pastoral families to settle, and the growing pull away from agrarian life for pastoral youth. Some argue that pastoralism is an archaic mode of subsistence unsuited to the demands of the modern world. Yet the world's great rangelands will continue to be dedicated to animal husbandry, all the more important as global populations and the demand for livestock products inexorably increase. Even if parts of the world's grasslands are diverted to wildlife conservation, mineral exploitation, irrigated or dry land agriculture, urban development or small-scale industry, much of the grasslands remote from urban centers will have no more productive use than extensive animal husbandry (Catley et al., 2013). The great alternative to pastoralism, which, recall, involves intensive use of labor to exploit land extensively, is ranching, which uses similar pastures to raise livestock for commercial ends using less labor due to the investment of capital in fencing, upgraded stock, fixed water points, feed supplements, veterinary medicine, motor vehicles, airplanes, modern communications, and so forth. In Botswana and Namibia, pastoralism has in many quarters given way to commercial ranching, under conditions of strict veterinary controls and restricted livestock movement, with the assurance of export agreements with the UK and the European Union. But in Kenya, land was taken from pastoralists at the beginning of the twentieth century, but commercial ranching enterprises there have never supplied more than a fraction of the national meat supply, that aimed at high-end restaurants and the urban bourgeoisie. In fact, the productivity of pastoral land use has proven higher than that of ranching, given the intensive investment of pastoral labor in raising and marketing livestock.

Where ranching thrives – in the US, Canada, Australia, and Argentina – settlers established enterprises on lands taken from indigenous peoples. What pastoralism has historically succeeded in doing is to enable the productive human habitation of the world's great grasslands, through an economic pursuit that supports an optimal number of people on land with few alternative uses, while efficiently providing growing local, national, regional, and global markets with livestock and meat. At present, a balance is maintained between available land, the number of livestock that can be supported on that land, and humans who can be productively engaged and employed in pastoral livelihoods. Population growth in the world's rangelands is largely absorbed in the diversification of rural

livelihoods and in the growth of small towns across savanna lands. Although many from pastoral communities will gain education, will come to appreciate national social services and urban amenities, and will grow distant from pastoral pursuits, some will remain on the land, changing to husbandry practices based on commercial models, using new skills, techniques, and technologies in adapting animal husbandry to new conditions. Pastoral futures will undoubtedly include mobile animal rearing in the grasslands, pursued by communities that bear the imprint of modernity while continuing to occupy dry regions of the globe (Galaty, 2013b).

Patenting in the Biological Sciences

This article is a revision of the previous edition article by A. Webster, volume 11, pp. 7612–7615, © 2001, Elsevier Ltd.

Abstract

This article traces the history of patenting products of nature with a view to explaining how it is that genes were deemed as patent eligible material by all major patent offices worldwide. The article concludes with a current discussion of the recent legal challenge mounted against gene patenting by the American Civil Liberties Union against Myriad Genetics' patents on the so-called breast cancer genes.

Introduction

In an interview after the announcement in 1955 of the success of the polio vaccine, Edgar R. Murrow asked Jonas Salk, "Who owns the patent on this vaccine?" Salk famously replied: "Well, the people, I would say. There is no patent. Could you patent the sun?" (As cited in Johnson, 1990.) Interestingly, Salk actually tried to patent the vaccine, but the application was rejected. Similarly, as Robert Kohler has demonstrated in his *Lords of the Fly*, the of the early twentieth century had a network of credit based on the sharing of mutant flies, techniques, and data. Personal credit and commercialism were deemed anathema to the collective spirit of scientific research (Kohler, 1994). At that time, geneticists enjoyed the openness of a scientific republic. By the 1970s, that was beginning to change, as intellectual property issues began to invade the biological sciences: the future of start-up biotech firms such as Genentech was predicated upon successful patenting of biological entities.

Commercialization of the biological sciences began in the 1970s with the rise of biotech firms (Shapin, 2008). Sheila Jasanoff has argued that the biotechnology industry in the United States could not exist as one now knows it without patent protection (Jasanoff, 2005). Biotech patents extended ownership rights to entities that had previously been considered to be outside the realm of patentability, rendering these objects as marketable commodities. Typically, in the early stages of a biotech company's existence, there were no marketable products. This was particularly true of the sequencing companies. Hence, intellectual property was the only source of credibility for a fledgling company looking to attract both corporate venture capitalists and less aggressive investors. Patents provided some assurance that there would be returns from future marketable products.

The theme of profiting from another person's body with a view to commodifying biological entities has of course been fraught with controversy and was the theme of a landmark California State Supreme Court Case, *Moore v. the Regents of California* (1990; see Rabinow, 1996; Boyle, 1996). It dealt with issues of commercialization and ownership of biological materials. A patient, John Moore, suffered from hairy-cell leukemia and was being treated by Dr David W. Golde of the University of California, Los Angeles Medical Center. Golde suggested that Moore's spleen be removed, and Moore signed the medical consent form, which stated that the hospital would dispose of, or cremate, any tissue removed from his body. Unbeknownst to Moore, Golde created a cell line from Moore's T-cells, clearly aware of the financial potential of such a research tool. The Regents of California received a patent on the cells in 1984. In 1983, Moore had been presented with another consent form, asking him to waive his rights to any profits from his cell line or any other type of tissue removed from his body. He refused to sign and showed the form to his lawyer, who then investigated and found out about the patent. Moore sued. The court opined that while Dr Golde was legally required to inform his patient that he had a financial interest in any samples removed from Moore's body, Moore did not have property rights to his T-cell line (Rabinow, 1996). In a similar, more tragic, example, Henrietta Lacks' family never received financial compensation for the immortal cell line (HeLa cells) derived from a tumor in her cervix (Skloot, 2010).

This desire for patent protection in the age of biocapitalism and biocolonialism, as numerous STS scholars have labeled it, however, raises an interesting conundrum (Pottage, 1995; Rajan, 2006). According to the product-of-nature doctrine, natural products are not patentable. So, how can one patent biological materials, the cornerstone of the biotech sector? The product-of-nature doctrine, while never explicitly invoked in a particular case, represents the accumulation of numerous US Supreme Court decisions disallowing the patenting of organisms or substances as they occur in nature. Simply stated, they are not inventions, and therefore are not patentable subject material. That said, as Beauchamp has recently argued, nineteenth-century Supreme Court rulings deemed some 50 years later as being relevant to the product-of-nature doctrine were not obviously so when they were originally decided (Beauchamp, 2013). The first Supreme Court decision relevant to the patenting of a natural product was the *American Wood Paper Company vs. Fibre Disintegrating Company* case (1874) (henceforth *American Wood-Paper Patent*), which revolved around the question of whether paper pulp (cellulose) extracted from wood via chemical processes and from a vegetable substance by means of chemical and mechanical processes could be patented. The mechanical process involved a machine that shreds the wood or vegetable substance into shavings, and the requisite chemical processes included a myriad of reactions, such as boiling in a strong alkali solution under high temperature and pressure,

chlorination, and washing with hydrochloric acid. The product, cellulose, was not patent eligible because it was well known at the time. That part of the patent failed due to prior art (Beauchamp, 2013).

Ten years later, the Supreme Court ruled on another case relevant to the patenting of a natural substance, *Cochrane v. Badische Anilin & Soda Fabrik* (1884). The reissued letters patent No. 4321 had been granted to C. Graebe and C. Liebermann of BASF for both the processes of producing alizarin, a compound found naturally in the root of the madder plant, and the composition of matter itself, which they called artificial alizarin. The Court ruled against composition-of-matter patent, concluding along the same lines as the *American Wood-Paper Patent* case that such a patent could not be awarded for artificial alizarin, since it is chemically equivalent to the naturally occurring substance, which was well known at the time. Again, it failed on grounds of prior art. The new method of production, however, was indeed deemed patentable.

The United State Patent and Trademark Office (USPTO) followed the rule established by these Supreme Court cases. In 1888, William Latimer applied for a process patent to extract the fibrous core from the center of the pine needles of Longleaf Pines (*Pinus australis*). He also applied for a composition-of-matter patent on the pine needles themselves as their centers could be used in the burgeoning textile industry. Citing these earlier cases – namely, *American Wood-Paper Patent* and *Cochrane* – the examiner argued that while the process was patentable, the product was not, as it was a product of nature, and therefore not an invention. The US Patent Commissioner affirmed the examiner's rejection in his *Ex parte Latimer* ruling (Harkness, 2011).

The Twentieth Century

Things were about to get interesting with respect to the patentability of natural products. *Parke-Davis & Co. v. H. K. Mulford Co.* (28 April 1911, 189 *Federal Register* 95), although not a Supreme Court case, was a patent-infringement case that raised the issue of patentability of biological entities. Indeed, this decision, written by Judge (Billings) Learned Hand, has been often referred to in the legal literature as the precedent for the early cases patenting of genes (Andrews, 2002; Doll, 1998). The case commenced with the affirmation of the patentability of a substance isolated from animal tissue that had therapeutic value, even though it differed from its natural homolog only in degree of purity. The key question was whether Parke-Davis' biochemist Jokichi Takamine's purification of adrenaline was sufficient to render it new therapeutically and commercially, and therefore patentable (Harkness, 2011).

Patent examiner James B. Littlewood, who was responsible for adjudicating the original patent application for Adrenalin – the commercial name for the mostly purified, patented adrenaline – in 1900 denied the patent multiple times after various revisions by the patentee on the grounds that it was a product of nature. Littlewood finally granted the patent on the seventh review on 2 June 1903. The critical point, however, was that Takamine's lawyers argued that 'Adrenalin,' the medical product, was something different from the naturally existing hormone (Harkness, 2011).

Adrenalin, of course, proved to be a rather important medical product. Not surprisingly, Parke-Davis & Co. jealously enforced their patent, and in 1905 engaged in a priority dispute with H. F. Mulford. The case now became one of patent infringement, and precious little was said about Adrenalin being a product of nature. The experts brought in by both sides did not address this issue of patenting natural products; they were interested only in matters of priority.

Priority was critical, since during the early years of the twentieth century, a number of adrenaline-based products were being sold in the United States and Europe. Specifically, Hoechst of Germany was marketing Suparenin, but Parke-Davis & Co.'s Adrenalin was relatively pure, safe, and efficacious (Dutfield, 2009). Interestingly, chemical and pharmaceutical substances were not patentable in Germany at that time. The first pan-German patent law, created after unification passed in May 1877, explicitly stated that the following inventions were excluded from patent protection: those "that, if developed, are against [the] law or good morals" (a sentiment that is also present today in European Patent Convention clause 53), and those "consisting of food, stimulants or therapeutic agents, as well as the invention of substances produced by means of chemistry if the invention does not include a specific production process" (as cited in Gaudillière, 2008). Unlike Britain, or the United States, chemical substances (including drugs) could not be patented in late nineteenth- and early twentieth-century in Germany. Schering was able to patent hormones in the 1920s and 1930s thereby establishing the precedents in Germany for subsequent patenting of purified biological substances (Gaudillière, 2008). Such a decision was seen to be in the interest of the public good and as such a monopoly on drugs was deemed both to be dangerous to the public welfare and to be deleterious to innovation. Patenting also seemed superfluous to the organic chemists who synthesized such substances. A cadre of top-notch German chemists could invent a myriad of processes, which of course could be patented, to produce a given chemical; hence, companies could create a wall of patent protection around a particular chemical substance. German chemists from August Wilhelm von Hoffmann to Paul Ehrlich and Carl Duisberg were renowned for their abilities in synthetic organic chemistry. German governmental officials worked closely with chemical company officials in order to draft and tailor the nation's patent law to the interests of the chemical industry (Dutfield, 2009). At the time, the American Pharmaceutical Association lobbied the federal government for weaker patent protection, as they argued that they were facing unfair competition from German companies. And they advocated in favor of changing the law such that only patents for chemicals processes and not the chemicals themselves could be patented in the United States. The government, however, did not change its stance.

Lacking a strong tradition in chemical synthesis, the burgeoning US and British pharmaceutical industries were centered on the extraction and purification of natural substances, rather than the organic synthesis of artificial substances (Lesch, 2007). Not surprisingly, in the United States this industry turned to patent laws, which starting with Judge Learned Hand's decision permitted the patenting of natural substances as long as they were isolated and purified.

Purification was crucial, as the United States introduced drug regulations in 1902 that required the establishment of a governmental laboratory to test and monitor new drugs for their safety and efficacy (Dutfield, 2009). American scientists were able to combine their practices with natural-product chemistry, fermentation, and endocrinology, with synthetic organic chemistry techniques gleaned from their research with German university chemists. Natural product-based companies, such as Parke-Davis, began to compete with the well-established German pharmaceutical companies. Indeed, from World War II to 1986, the patenting of products of nature in the form of antibiotics, hormones, and vitamins was dominated by the United States and, to a lesser extent, the United Kingdom (Achilladelis, 1993). In short, two different patent regimes helped to foster two different research traditions. In the Anglo-American world, which included the United States, United Kingdom, and Canada, pharmaceutical research was centered on physiological chemistry and the isolation and purification of natural products from plants, animals, and humans, whereas in Germany and Switzerland, such research was predicated on synthetic organic chemistry being carried out not only in universities but also in research laboratories of the dyestuff industries. These chemists synthesized the active principles found naturally in plants and animals and improved upon their natural analogs for use as medications.

On 28 April 1911, in his landmark ruling in *Parke-Davis*, Judge Hand of the District Court for the Southern District of New York upheld Takamine's patents, famously arguing:

> But, even if it [Adrenalin] were merely an extracted product without change, there is no rule that such products are not patentable. Takamine was the first to make it available for any use by removing it from the other gland-tissue in which it was found, and, while it is of course possible logically to call this a purification of the principle, it became for every practical purpose a new thing commercially and therapeutically. That was a good ground for a patent. … The line between different substances and degrees of the same substance is to be drawn rather from the common usages of men than from nice considerations of dialectic.
>
> (28 April 1911, 189 *Federal Register* at 103)

The patenting of the first generation of hormones in general, and adrenaline in particular, proved to be a challenge to what was now in the 1920s seen as the well-established product-of-nature doctrine in the United States, since the hormones were not created artificially (i.e., synthetically), but were isolated and purified from nature. While Hand's ruling undoubtedly benefited the US pharmaceutical companies in gaining the lead over their German counterparts, it also increasingly blurred the boundary between natural and artificial, nonpatentable and patentable (Dutfield, 2009). This case paved the way for the subsequent patenting of sex hormones, steroids, vitamins, and antibiotics in the United States (Achilladelis, 1993; Dutfield, 2009). Although penicillin was never patented (the processes for its mass production of course were), most antibiotics thereafter were patented despite being products of nature.

In 1930, Congress passed the Plant Patent Act, which permitted patents to be issued to persons who had "invented or discovered and asexually reproduced any distinct and new variety of plant, other than a tuber-propagated plant" (as cited in Kevles, 2007; see also Bugos and Kevles, 1992). Congress did query whether or not this act would contradict the product-of-nature doctrine, and whether a new variety of plant would be considered an invention or discovery, and consequently if the breeder should be considered an inventor. The House Committee on Patents argued that, although a new plant variety was indeed a product of nature, it was created through human intervention. The plants had characteristics, which differed from those that grew in the absence of human agency. The link between biological and chemical entities was established early on, as the House Committee insisted upon the analogy between "the part played by the plant originator in the development of new plants and the part played by the chemist in the development of new compositions of matter" (cited in Bugos and Kevles, 1992). The House Committee ruled that a new variety of plant that was cultivated (rather than found in the field) was a type of discovery worthy of patent protection, and its cultivator was the discoverer. Patent protection at this point did not extend to seeds, as those skilled in the art at the time believed that 'invented' seed plant varieties were too unstable across generations. The topic of patenting subsequent generations via seeds and genes became highly controversial decades later.

While decisions of the USPTO seemed confused and contradictory, no such ambiguity seemed to exist at the level of the Supreme Court, whose decisions of the 1920s through 40s paralleled the cracking down on patents by the Antitrust Division of the Department of Justice (Beauchamp, 2013). In 1948, the Supreme Court ruled on the case, *Funk Brothers Seed Co. v. Kalo Inoculant Co*. Kalo Inoculant sued Funk Brothers for patent infringement, which claimed the product and process of creating a mixture of root-nodule bacteria for inoculating legumes. Funk Brothers argued that the patent was invalid. Kalo's patent included six strains of naturally occurring bacteria, each of which could be used to fertilize some legumes without inhibiting the actions of the others. The patent holder combined these strains so that a farmer could purchase one fertilizer for various plants, rather than one for each type of plant (McGarrigle and Norviel, 2008). The bacterial strains did not inhibit one another. The Seventh Circuit ruled that the inventor had produced new and different composition of noninhibitive strains, which possessed utility (253 F.2d 156; 116 U.S.P.Q. 484). The Supreme Court disagreed, arguing that the implementation of a natural principle or phenomenon was not patentable. Indeed, the properties of each strain of bacteria were exactly those exhibited in nature, even though the combination had utility.

The ruling of the Supreme Court not withstanding, mixed signals were being sent from the lower courts. *Merck & Co., Inc. v. Olin Mathieson Chemical Corporation* of 1958 was the relevant case for patentability tried after the passing of the Patent Act of 1952 (253 F.2d 156; 116 U.S.P.Q. 484). In 1926, scientists discovered that patients suffering from pernicious anemia could benefit from adding a large quantity of cattle liver to their diets. Some 20 years later, new liver extracts could be administered to patients; however, they were expensive, and not all patients could tolerate them. At that time, biochemists could not isolate or identify the specific agent responsible for the improvement in the patients' health. Dr Mary S. Shorb,

a bacteriologist at the Department of Agriculture and later at the University of Maryland, developed an assay with a microorganism, *Lactobacillus lactis Dorner* (or LLD), to discover this unknown agent. In 1947, she entered into a collaboration with scientists at Merck, one of whom was Thomas R. Wood, who had been working on this unknown compound since 1938. Wood hired a chemist, Edward L. Rickes, and in October 1947 they isolated a pinkish compound, which upon further purification and concentration turned out to be a red crystalline material, which they subsequently named vitamin B_{12}.

In 1957, the district court ruled that the patent of vitamin B_{12} was invalid on the grounds that it was a product of nature and that there was a lack of invention. In reversing the decision a year later, the US Court of Appeals for the Fourth Circuit specifically addressed the 'product of nature' defense. The court interpreted the Patent Act of 1952 as not precluding products of nature for patent eligibility as long as they were new and useful. The court ruled that, contra the *American Wood-Paper Patent*, the vitamin B_{12} produced was new, and it possessed unique properties vis à vis the naturally occurring substance. The US pharmaceutical industry lobbied to ensure that the 1952 Patent Act would permit the patenting not just of vitamins but also of discovered antibiotics as well as the techniques of their mass production and screening (Kingston, 2004; Dutfield, 2009).

Throughout the 1960s and 1970s, more rigorous agricultural intellectual property statutes were being sought in the United States due to the Green Revolution shepherded by Norman E. Borlaug, as well as the rising domestic seed market and seed industry (Bugos and Kevles, 1992). On 2 December 1961, an International Conference for the Protection of New Plant Products in Paris created the Union International pour la Protection des Obtentions Végétales, or UPOV. Initially, UPOV sought intellectual property protection of plant varieties by means other than patents. Since the United States declined to join unless patents were included in such protection, the UPOV acquiesced, and in 1978, patents were granted on patent-eligible plants internationally.

The key to this more recent legislation, then, is the relationship between the patented entity and its natural homolog. Products of nature are only rendered patentable if, by virtue of human hand bringing about the isolation and purification, the new substance is different in kind from the natural product, echoing Learned Hand's sentiment (Sweet, 2010).

1980s and 1990s: The Post *Diamond v. Chakrabarty* World

The 1980 *Diamond v. Chakrabarty* ruling is the only Supreme Court case cited as precedent for the patenting of genes (447 U.S. 303 (1980)). While working at General Electric, the microbiologist A. M. Chakrabarty created a new bacterium of the *Pseudomonas* genus. The initial utility claimed by Chakrabarty for this artificial bacterium was the production of proteins from the degradation of hydrocarbons (Kevles, 1994). Later, it became clear that this bacterium possessed the coveted attribute of being able to break down crude oil into biodegradable materials. Clearly, such a quality was applicable to oil spills. At the time of his patent application, there were four known species of bacteria that could metabolize different components of crude oil. These species, however, competed with each other, thereby limiting the amount of oil they could convert. Chakrabarty took the genes coding for the proteins that degrade the oil and cloned them in bacterial vectors. Irradiating the bacteria with ultraviolet light after introducing the genes into the recombinant DNA vectors, he discovered a method for cross-linking that resulted in all four genes being present in one bacterium. This newly created bacterium could degrade two times more oil than the four original species of bacteria. We are speaking here of a bacterium that clearly was the product of human hands, as it did not exist before Chakrabarty's invention, and it was unlikely that the natural bacteria could break down more components of the oil.

A significant amount of human intervention was required, and such intervention needed to render the artful product sufficiently different from other types of naturally existing *Pseudomonas* bacteria (Palombi, 2004). In short, while it cannot be accurately claimed that it serves as a legal precedent for gene patenting, it can be argued that *Diamond v. Chakrabarty* set the milieu for the patenting of genes. This case marks the first of many victories of the biotech industry to alter biotech patent rules in ways that suited their financial interest (Dutfield, 2009).

Their next round of biotech's successes occurred 2 years later. Intellectual property (IP) lawyers persuaded the USPTO and the courts that genes were chemical compounds; hence, chemical IP could be applied to biotech patents. With this reasoning, one of the first gene patents – the Adrenocorticotropin-lipotropin precursor gene, US Patent 4 322 499 – was awarded in March 1982 (Calvert and Joly, 2011). The analogy between genes and chemicals seemed a perfect one for the USPTO, since patent law in the United States had by this time reached a stage whereby the patenting of isolated and purified natural products was well established (Conley and Makowski, 2003; Demaine and Fellmeth, 2002). This decision went unchallenged until the end of the 1990s, when scientists from leading research institutions began to query the sagacity of reducing genes to chemical compounds (Calvert and Joly, 2011).

Diamond v. Chakrabarty paved the way for the patenting of life forms. In 1988, the USPTO granted a patent on living animal for the first time in the office's history: Harvard's oncomouse, a genetically engineered rodent that was predisposed to cancer (Kevles, 2002). DuPont Corporation, which had given Harvard $6 million to fund research on the oncomouse, enjoyed an exclusive license for its use (Kevles, 2002; Haraway, 1997). Much like Chakrabarty's *Pseudmonas* bacterium, the transgenic mouse did not exist in nature. Although it was clearly a living mammal, it was the creation of human hands in the laboratory. As Fiona Murray astutely points out, the oncomouse changed the so-called cycles of credit in the academy (Murray, 2011). DuPont's commercial economy based on its exclusive license seemed to many to be antithetical to the scientific, moral economy of knowledge sharing. That moral economy is now often regarded as an antiquated model. Many academic scientists own patents in this new age of the academic economy of credit. Patents establish a new type of credit distinct from and in addition to the published paper. Not all scientists with patents, however, enter into exclusive licensing agreements with biotech firms.

Canada, Europe, and the United States

The oncomouse case is an illustrative one, as it shows the differences among three major patent offices despite attempts by Trade-Related Aspects of Intellectual Property Rights to harmonize patent law worldwide. In 2002, the Supreme Court of Canada opined that higher forms of life were not patent eligible since they were not manufactured within the meaning of invention of the Patent Act of 1869. While microorganisms might be the result of a human mixture and therefore patent eligible, the body of a mouse is not. Unlike the USPTO, the European Patent Office (EPO) considered issues of morality, which have played a much larger role in European patent deliberations (Jasanoff, 2005). Indeed, article 53 of the European Patent Commission cites two areas where patents are to be negated: first, if they are deemed to be contrary to 'ordre public' or morality, and second, if they are applied to plant or animal varieties, or essentially biological processes for the production of plants and animals. In 2004, the EPO ruled that the oncomouse patent was indeed valid. They did not consider the oncomouse an animal variety, but rather a product of human intervention. With respect to the ordre public clause, they reckoned that the benefits humans gained from the creation of the oncomouse outweighed the transgenic rodent's suffering.

Genes are considered patentable by all major patent offices. Article 5(1) of the European Union (EU) biotech directive states: "The human body, at the various stages of its formation and development, and the simple discovery of one of its elements, including the sequence or partial sequence of a gene, cannot constitute patentable inventions" (as cited in Jasanoff, 2005). Articles 5(2) and 5(3), however, state that isolated gene sequences may be patented, even if their sequences are identical to those occurring in nature, if they are derived by a technological procedure and they possess an identifiable industrial application. France initially objected to the patenting of human genes, and would not support the EU biotech directive until it finally acquiesced and signed on in 2004. Germany and France have provisions in their law narrowing the scope of biotech patents to the recited utility. These provisions apply only to biotech patents, and are highly controversial.

Between January 1980 and December 2003, 15 603 patent families claiming human DNA sequences were patented. Of those sequences, 94% received at least one patent from the USPTO, while less than 5% (750) were granted at least one patent by the EPO (Hopkins et al., 2007). The larger health care market the United States offers, the longer time it takes for the EPO to review patents, and the EPO's higher bar of patentability all contribute to those skewed numbers. The three major US sequencing companies (Human Genome Sciences (HGS), Incyte, and Millennium Pharmaceuticals) have found it particularly difficult to have their patent applications approved by the EPO. As of 2005, Incyte had only two European patents granted out of 485 applications, while Millennium had no patents out of 94 applications, and HGS had no patents out of 378 applications. The EPO's more stringent requirements for specific utility claims and the insufficiency of sequence homology to establish functional/utility claims combine to explain those paltry figures. Indeed, the EPO's stance reflects a much greater awareness of, and concern with, gene patenting among Europeans.

American Civil Liberties Union vs. Myriad Genetics

Most recently, the question of patenting natural products was the key issue in the controversial ruling in the United States of Judge Robert W. Sweet of the US District Court of Southern New York. The case, *Association for Molecular Pathology et al. vs. USPTO et al.* (henceforth, the Myriad Case), is an attempt by numerous scientific and medical organizations headed up by the American Civil Liberties Union (ACLU) to render Myriad Genetics' breast cancer (BRCA) 1 and 2 gene patents invalid by arguing, among other things, that genes are products of nature and therefore are not patentable as defined in section 101 of US patent law (Parthasarathy, 2007). In March 2010, Judge Sweet ruled that the Supreme Court precedent declares that products of nature are not patentable unless "a change [is made] that results in the creation of a fundamentally new product" (Sweet, 2010). In short, "markedly different characteristics" are, according to Sweet's interpretation of previous Supreme Court rulings, critical to satisfy section 101 of US patent law (447 U.S. 303 [1980] at 310).

Myriad's attorneys responded to Sweet's ruling by appealing to the US Court of Appeals for the Federal Circuit (CAFC) (Brief for the Appellants, No. 2010-1406.) The Acting Solicit General, Neal Katyal, intervened on 4 April 2011, marking the first time that the top legal advocate of the executive branch appeared before the CAFC (Frankel, 2011). He did not support the USPTO's position that isolated DNA molecules are patentable, rather he urged a compromise via the so-called magic microscopic test. If an imaginary microscope could focus on a claimed DNA sequence as it exits in the human body, then the DNA is a product of nature, and therefore not patentable (Lourie, 2011). Accordingly, since BRCA 1 and 2 genes could, in principle, be seen with this magical microscope, they should not be patentable. This microscope, however, could not find cDNA sequences in the human genome, since cDNA is the product of the human hand and is, in his view, therefore patentable.

The CAFC did not seem to be persuaded by this analogy. By a vote of two to one, they ruled on 29 July 2011, that Myriad's patents on isolated sequences of DNA were patent eligible, thereby reversing Judge Sweet's decision of March 2010. Judge Alan D. Lourie of the CAFC concluded that genes are indeed patentable, as they "have a distinctive chemical identity and nature from molecules that exist in nature" (Lourie, 2011). DNA sequences are not contained within a physical mixture, and unlike uranium or adrenaline they cannot be purified; they must be chemically cleaved from their linkage with other genetic materials. Or, as Lourie explains, "[i]n other words, in nature, isolated DNAs are covalently bonded to such other materials. Thus, when cleaved, an isolated DNA molecule is not a purified form of a natural material, but a distinct chemical entity" (Lourie, 2011).

Federal Circuit Court Judge Kimberly A. Moore concurred with Lourie; however, her reasoning was slightly different (Moore, 2011). Pace Lourie took *Funk Brothers* and *Chakrabarty* as the precedent cases for establishing the

criteria of patentability; however, she argued that a mere purification of a substance is normally insufficient grounds for patentability. Moore turned to the chemical structure of DNA fragments to argue for their uniqueness and artificiality. Fragments, which include DNA isolates, have different chemical properties than the parent molecule from which they were removed.

In addition, cDNA does not exist in nature: it is the product of the laboratory after adding reverse transcriptase to mRNA. cDNA does not have the same sequence as mRNA (indeed, it has the complementary sequence), and because cDNA contains thymine while mRNA contains uracil and deoxyribose sugar as opposed to ribose, cDNA is more stabile than mRNA. Therefore, cDNA is, in Moore and Lourie's views, patentable. Moore never discussed the nonobviousness criterion, however, which (ironically) becomes an obvious problem if cDNA is patentable but isolated DNA is not.

What about DNA sequences that have the same sequence as the DNA of the gene found in nature? For Moore this was a different, and more complex, issue. She reasoned the fact that these smaller isolated DNA sequences are a part of 'the larger chromosomal polymer' does not render them unpatentable. These molecules are not quite analogous to naturally occurring minerals; rather, isolated DNA molecules possess different chemical ends than the naturally occurring DNA of the chromosome (Moore, 2011).

The last portion of Moore's opinion is rather disquieting. There, she expressed the fear that since USPTO had granted tens of thousands of patents on isolated nucleic acid sequences and purified natural products for decades,

> Changing course years after the fact will only serve to punish those companies who made the reasonable decision to invest large amounts of time and money into the identification, isolation, and characterization of genes. Unsettling the expectations of the biotechnology industry now, based on nothing more than unsupported supposition, strikes me as far more likely to impede the progress of science and useful arts than advance it. Given the complicated technology and conflicting incentives at issue here, any change must come from Congress.
>
> (Moore, 2011: p. 28 of her ruling, p. 83 for the pdf document.)

She concluded: "We cannot, after decades of patents and judicial precedent, now call human DNA fruit from the poisonous tree, and punish those inquisitive enough to investigate, isolate, and patent it" (Moore, 2011: pp. 31–32 of her ruling, pp. 85–86 of the pdf.).

The third Federal Judge hearing the appeal was William Curtis Bryson. Although he concurred with the majority ruling that Myriad's cDNA and methods claims are patentable (except for the diagnostic method claim, which all three judges thought was invalid), he was rather adamant that isolated genes are not patent-eligible (Bryson, 2011). He was particularly unconvinced that an isolated human gene differed from a 'native gene.' He feared that the majority ruling would have serious adverse effects on research and treatment. Pace Moore and Lourie, and Bryson drew upon *Chakrabarty* and *Funk Bros.* for defining patentable substances; however, unlike them he felt that although gene extraction might be difficult, isolated genes "are analogous to the 'new mineral discovered in the earth,' or the 'new plant found in the wild' that the Supreme Court referred to in *Chakrabarty*" (Bryson, 2011).

In December 2011, the ACLU appealed the CAFC's ruling to the US Supreme Court, which granted a writ of certiorari on 26 March 2012. The case was remanded back to the CAFC for further consideration in light of *Mayo Collaborative Services* v. *Prometheus Laboratories, Inc.*, 566 U.S. (2012). The opinion was written by Justice Breyer who in *Labcorp v. Metabolite* wrote a dissent to a decision by the Court majority not to take the case. In *Mayo*, the US Supreme Court ruled 9–0 that natural laws may not be patented standing alone or in connection with processes that involve "well-understood, routine, conventional activity." The case involved Prometheus' method claims involving administering a drug to a subject, determining a metabolite concentration in the subject's blood, and inferring the need for a change in dosage based on concentration. The Court opined that the methods were not patent-eligible subject matter since they contributed nothing inventive to the law of nature that formed the basis of their claimed invention.

On 20 July, the CCAF reconsidered the case, and on 16 August, they offered their ruling. The original three judges' opinions remained unchanged, confirming their original decision that genes are patent eligible by a vote of two to one. Lourie, once again representing the majority, argued that isolated DNA molecules have chemically different ends from naturally occurring DNA; therefore, they are patent eligible. An interesting aspect of Judge Lourie's opinion is his attempt to distance himself from the public policy implications of the decision:

> [i]t is important to state what this appeal is not about. It is not about whether individuals suspected of having an increased risk of developing breast cancer are entitled to a second opinion. Nor is it about whether the University of Utah, the owner of the instant patents, or Myriad, the exclusive licensee, has acted improperly in its licensing or enforcement policies with respect to the patents. The question is also not whether is it desirable for one company to hold a patent or license covering a test that may save people's lives, or for other companies to be excluded from the market encompassed by such a patent — that is the basic right provided by a patent, *i.e.*, to exclude others from practicing the patented subject matter. It is also not whether the claims at issue are novel or nonobvious or too broad. Those questions are not before us. It is solely whether the claims to isolated BRCA DNA, to methods for comparing DNA sequences, and to a process for screening potential cancer therapeutics meet the threshold test for patent-eligible subject matter under 35 U.S.C. § 101 in light of various Supreme Court holdings, particularly including *Mayo*. The issue is patent eligibility, not patentability.
>
> We would further note, in the context of discussing what this case is not about, that patents on life-saving material and processes, involving large amounts of risky investment, would seem to be precisely the types of subject matter that should be subject to the incentives of exclusive rights. But disapproving of patents on medical methods and novel biological molecules are policy questions best left to Congress, and other general questions relating to patentability and use of patents are issues not before us.
>
> (Lourie, 2012: pp. 1324–1325)

In light of the *Mayo* decision, Lourie argued against the assumption that Myriad's composition claims are merely reflections of a law of nature.

Pace Lourie and Moore argued that *Funk Brothers* and *Chakrabarty* were more relevant to the case than *Mayo*; however, *Mayo* was informative regarding the scope of the law of nature exception. Using all three cases, Moore reckoned that there were two principles involved, namely, that laws or manifestations of nature are not patentable and whether the patented DNA fragments were (as stated by Bryson in his dissent) compositions of matter with "markedly different characteristics from that found in nature with the potential for significant utility is directed to patentable subject matter" (Bryson, 2012: p. 1340). To the first principle, she reiterated her stance that isolated DNA fragments possess truncations with different ends than naturally occurring DNA, and hence constitute an artificial construction of the human hand. To the second point, she concluded that these fragments do indeed possess markedly different characteristics from their natural homolog, and they do possess utility. Hence, they are patentable subject matter.

Bryson also applied *Mayo* to the case, but came to a different conclusion, stressing that the changes made to the DNA were not inventive, but merely incidental, and thus insufficient to warrant a patent. The majority stressed the uniqueness of patented DNA sequences based on structure, whereas Bryson turned to the informational content, as Judge Sweet did in the District Court ruling. He reasoned that such a move was an appropriate one in the light of *Mayo*, and asserted that DNA's informational content was a critical characteristic. Since the information encoded in the claimed isolated sequences was identical to that found in nature, the sequences were not markedly different from those found in nature (689 F.3d 1355). The ACLU appealed the CAFC's second decision to the Supreme Court, which on 30 November 2012, decided that they would hear the case in the spring of 2013.

On 13 June 2013, the Supreme Court decided by a vote of nine to zero that genes merely excised from the genome were not patent eligible; they were products of nature and not a result of invention. They did, however, rule that cDNA was an artificial construct created in the laboratory and therefore was patentable.

Ever since the 1980s, the USPTO, Congress, and the CAFC have ceded much ground to certain members of the biotech industry by lowering the bar for patent eligibility, utility, and nonobviousness. What makes this case so interesting is that the Biotechnology Industry Organization is split over the issue of gene patenting. While sequencing companies have obviously benefitted from gene patenting, a number of pharmaceutical companies have opposed such IP protection, since they need to pay royalties or licensing fees to patent holders in order to develop diagnostic tests and therapeutic drugs relevant to gene products.

Times might just be changing. Certainly the major patent offices have become more stringent with adjudicating gene patents over the past decade. While the number of gene patents increased considerably during the 1990s, that number has decreased significantly during the first decade of the new millennium (Hopkins et al., 2007). The proportion of gene-patent applications granted by the EPO by September 2005 decreased from 45% of those submitted in the 1980s, to 8% of those submitted between 1996 and 2000. And some commentators conjecture that a number of patents will be abandoned prematurely, as either technical problems prove insurmountable or commercial viability becomes limited. For example, only 70% of the USPTO DNA patents awarded in the early 1990s were still maintained by 2005. Gene-patent filing at all three major patent offices declined sharply after the Human Genome Project made the human genome sequence public in 2001, thereby rendering the novelty criterion problematic. Many of the post-2001 applications are still in the examination phase. Numerous patentees interviewed felt that they were now faced with significant challenges, such as more stringent criteria for demonstrating utility, novelty, nonobviousness, full written description, and unity of invention (i.e., the parts of the invention are intrinsically linked). And some – but certainly not all – commentators argued that the USPTO's Revised Utility Guidelines of 2001 had raised the bar on patent eligibility. In short, the publication of the human genome and stricter requirements placed on gene patent applications have resulted in a decreased number of patent applications and patent awards awarded during the first decade of the century. Speculative, broad utility claims such as the ones granted by the USPTO in the 1990s just might be a thing of the past.

Pathological Gambling and Gambling Disorder

David M Ledgerwood, Wayne State University School of Medicine, Detroit, MI, USA
Nancy M Petry, University of Connecticut Health Center, Farmington, CT, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Pathological gambling is a psychiatric disorder that affects 0.4–1.8% of the adult population and is associated with debt, bankruptcy, illegal behaviors, family/social conflict, vocational/educational problems, and psychiatric and substance abuse comorbidity. Pathological gambling has been reclassified in the Substance-Related and Addictive Disorders category of the *Diagnostic and Statistical Manual for Mental Disorders*, Fifth Edition, and has been renamed gambling disorder. This article provides an overview of pathological gambling diagnostic classification, epidemiology, etiology, and treatment.

Pathological gambling (PG), recently renamed gambling disorder (GD), is a psychiatric disorder that has been characterized as an impulse control disorder in the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) until its recent placement as a non-substance-related disorder in the Substance-Related and Addictive Disorders section of the 5th edition (DSM-5, American Psychiatric Association, 2013). Briefly, it is characterized by "persistent and recurrent maladaptive gambling behavior that disrupts personal, family, or vocational pursuits." GD is associated with many debilitating problems including financial indebtedness, bankruptcy, legal and vocational difficulties, and interpersonal conflict (Petry and Armentano, 1999). Individuals with GD also are more likely to experience several other co-occurring psychiatric and substance abuse conditions including mood, anxiety, and personality disorders; heightened suicide risk; and alcohol and drug abuse (Petry et al., 2005). In this article, GD symptoms, classification, epidemiology, etiology, and treatments are reviewed.

Classification of Pathological Gambling and Reclassification for DSM-5

PG was first introduced as a Disorder of Impulse Control, Not Elsewhere Classified in the DSM-III, and the disorder remained in the section for impulse control disorders in the DSM-IV. Based on increasing research evidence revealing that PG may have several characteristics in common with substance use disorders, however, PG has been reclassified for the DSM-5 alongside alcohol and other substance use disorders in the section titled Substance-Related and Addictive Disorders (APA, 2013).

As of May 2013 with the publication of the DSM-5, PG has been renamed gambling disorder. According to the DSM-5, to be diagnosed with GD, an individual must meet at least four of nine symptoms. These symptoms include (1) preoccupation with gambling or ways to get money with which to gamble; (2) needing to gamble with increasing amounts of money to experience excitement; (3) restlessness or irritability when not gambling; (4) repeated unsuccessful attempts to cut down or stop gambling; (5) using gambling as a way to escape from problems or relieve painful affect; (6) chasing gambling losses; (7) lying to close others to conceal the extent of gambling involvement; (8) jeopardizing important relationships, jobs, or educational opportunities because of gambling; and (9) relying on others for financial bailouts from desperate financial situations caused by gambling. One symptom, engaging in illegal activities to support gambling, was dropped from the DSM with the 5th edition, and the number of symptoms needed to meet diagnostic criteria was decreased from five to four. The gambling symptoms must not exclusively occur during a manic episode. For the remainder of this article, the authors primarily use the term PG because nearly all of the current research literature is based upon this older formulation of GD.

Epidemiology

Prevalence rates of PG have been established in several general population surveys conducted in many countries. The National Gambling Impact Study Commission (Gerstein et al., 1999) conducted a survey of 2417 randomly selected US adult residents. In this study, lifetime rate of PG was 0.8% and lifetime rate of problem gambling (subthreshold PG reflected in meeting three or four PG symptoms) was 1.3%. Past-year rates of PG and problem gambling were lower at 0.1 and 0.4%, respectively. Another national telephone survey around that same time of 2638 randomly selected US adults found somewhat higher lifetime prevalence rates of 2.0 and 2.8% for PG and problem gambling, respectively (Welte et al., 2001).

Two additional US surveys utilized data from the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC) and the National Comorbidity Survey Replication (NCS-R). The largest survey to date, the NESARC, included in-person interviews of over 43 000 adults. A lifetime PG rate of 0.4% was established in this survey (Petry et al., 2005). The NCS-R survey found a similar lifetime PG rate of 0.6% among 9282 adult respondents (Kessler et al., 2008). This survey also reported higher lifetime problem gambling rates of 2.3%.

Other countries with legalized gambling have similar prevalence rates to the United States. One recent study compared prevalence rates from several countries, including Australia, Canada, China, Italy, New Zealand, Norway, Singapore, Sweden, Switzerland, United Kingdom and the United States (Stucki and Rihs-Middel, 2007). Weighted mean prevalence rates for both pathological and problem gambling were similar to the above studies from the United States, at 0.8–1.8% for PG and 1.2–2.4% for problem gambling. Thus, prevalence rates tend to be similar across countries with legalized gambling.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21007-6

Prevalence rates also tend to be higher for adolescents and young adults than they are for adults. One large-scale telephone survey that examined both populations in the United States found that the prevalence of problem gambling among respondents age 14–21 years was 2.1% (Welte et al., 2008).

Etiology

Demographic Correlates

Several demographic factors appear to be associated with a higher risk of PG (see Petry, 2005 for a review). Age, for example, appears to be inversely related to gambling problems, as indicated by prevalence studies cited above that find higher rates of PG among younger individuals. Gender is also a contributing factor, as men have traditionally been at substantially higher risk for developing PG than women, although there is also some evidence that the gap between men and women has been narrowing with the proliferation of legal gambling venues.

Other demographic factors that may incur some increased risk for PG include race, socioeconomic status, and marital status. Across countries with legalized gambling, PG tends to be more prevalent among racial and ethnic minorities. In the United States, for example, the current literature consistently shows that PG is more prevalent among African Americans, Hispanics, and Native Americans than it is among European Americans (e.g., Kessler et al., 2008; Welte et al., 2001). Across countries with legal gambling and majority populations of European heritage, higher rates of PG have been found among all nonwhite groups in the population, including those of Asian, Hispanic, Pacific Islander, and Indigenous background (see Petry, 2005 for review).

Lower socioeconomic status has also consistently been found to be associated with PG (Petry, 2005). The effect of socioeconomic status on the rates of PG is somewhat difficult to interpret because it may be confounded by other factors that may also correlate with poverty such as nonmajority racial/ethnic status or co-occurring psychopathology. However, most studies show that lower income earners are overrepresented among pathological gamblers, and there are some studies that show lower education and disability status to be associated with higher rates of PG (e.g., Morasco and Petry, 2006; Welte et al., 2001).

Marital status also appears to be associated with PG status (Petry, 2005). Specifically, studies have often found that pathological gamblers are more likely to be divorced, separated, and/or never married relative to nonproblem gamblers. There are several possible reasons for the relationship between PG and marital status (e.g., being single may place one at greater risk of PG because there are fewer external controls over gambling behavior; pathological gamblers may be less able to form stable relationships because of underlying psychopathology). However, the etiological role of being single is not fully understood.

Psychiatric Comorbidity

Psychiatric and substance use disorders are highly comorbid with PG. In the United States, population surveys have demonstrated that individuals with PG have very high rates of mood, anxiety, substance use, and personality disorders (Petry et al., 2005). A recent meta-analysis examined comorbidity across 11 population-based studies of problem and/or pathological gamblers conducted in Canada, United States, Korea, and Switzerland (Lorains et al., 2011). Although there was significant heterogeneity across studies, this meta-analysis revealed that globally pathological gamblers experience high rates of nicotine dependence (60.1%), substance use disorder (57.5%), mood disorder (37.9%), and anxiety disorder (37.4%).

Etiological models of PG suggest that there may be different subtypes of PG, and that the subtype may depend in part on the extent to which co-occurring psychiatric conditions contributed to the development of the disorder. The most frequently discussed model is the Pathways model, which presumes that the etiology of PG takes one of three primary courses: (1) behaviorally conditioned gambling in which the pathological gambler develops problems primarily as a result of the contingencies associated with the games themselves, rather than any underlying psychopathology; (2) escape gambling where the PG develops primarily as a maladaptive coping strategy to alleviate painful affect associated with depression and/or anxiety disorders; or (3) antisocial-impulsive gambling, which includes elements of behaviorally conditioned and escape gambling, and is also characterized by greater underlying impulse control problems that often manifest themselves in the form of illegal activities, antisocial personality, and impulse control problems (Blaszczynski and Nower, 2002). For the most part, studies support the possibility that these three underlying subtypes of PG may exist (see Milosevic and Ledgerwood, 2010 for review). However, the question of whether underlying depression, anxiety, or antisocial disorders precede the development of PG, or impact its treatment, is not yet settled.

Impulsivity and Neurobiological Factors

Impulsivity is a personality construct that is often broadly defined as a tendency to act without forethought. Impulsivity has been operationally defined in many ways including as inattention, response disinhibition, rate of discounting of delayed rewards (in favor of smaller, immediate rewards), risk-taking, sensation seeking, and others (Evenden, 1999). It is a trait that is almost universally found to be elevated in PG (see Van Holst et al., 2010 for review). Indeed, some results show that impulsivity in childhood may predict later problem gambling (Pagani et al., 2009). Further, neurodevelopmental changes that occur during adolescence in pathways associated with reward and impulsivity may place some at greater risk for gambling later in life (see Chambers and Potenza, 2003 for review). These recurring findings regarding the relationship between gambling and impulsivity have led to recent attempts to understand the neurobiological underpinnings of impulse control problems experienced by pathological gamblers.

Neurobiological studies of pathological gamblers have found similarities with individuals who have substance use disorders in frontal and limbic/striatal system functioning (e.g., Reuter et al., 2005). Imaging research with substance-abusing individuals has revealed deficits in activation of the orbitofrontal cortex and dorsolateral prefrontal cortex (Bolla et al., 2005). Functional magnetic resonance imaging studies of pathological gamblers and healthy controls reveal that

pathological gamblers experience deficits in functioning in frontal areas of the brain associated with executive function and decision making (e.g., orbitofrontal cortex, caudate/basal ganglia, thalamus, ventromedial prefrontal cortex, and ventral striatum; e.g., Potenza et al., 2003). Exposure to gambling cues may also be associated with increased activity in executive function areas of the brain such as the dorsolateral prefrontal cortex in pathological gamblers relative to controls (Crockford et al., 2005). Furthermore, other studies have found significant differences between pathological gamblers and controls in function in the ventral striatum and limbic system structures (Miedl et al., 2010; Reuter et al., 2005). Indeed, Reuter et al. (2005) found reduced activation in the ventral striatum and ventromedial prefrontal cortex among pathological gamblers during a gambling task, suggesting hypoactivation of mesolimbic reward pathways relative to healthy controls.

Nonimaging studies have also found reason to suspect neurological deficits among pathological gamblers. For example, it appears that problem gamblers exhibit differential neurotransmitter activation relative to healthy controls. Moreno et al. (1991) demonstrated that pathological gamblers show blunted prolactin response indicating 5-hydroxytryptamine (5-HT) hypoactivity. Similar findings of differential functioning between problem gamblers and controls have also been found in studies of the dopaminergic system (Bergh et al., 1997). Research has also demonstrated that variants of the DRD2 dopamine receptor gene may also be a risk factor for the development of GDs (Commings et al., 1996).

There is further evidence that pathological gamblers experience impaired decision making and planning and cognitive flexibility deficits indicative of impaired executive function (Goudrian et al., 2006; Ledgerwood et al., 2012). Goudriaan et al. (2006) also reported an absence of physiological arousal (e.g., increased heart rate) in pathological gamblers exposed to win scenarios on the Iowa Gambling Task. Taken together, these neurobiological findings point to likely deficits in executive function and decreased reward sensitivity among pathological gamblers that serve to maintain problematic gambling behavior. For many pathological gamblers, these deficits may also contribute to the development of the disorder, but longitudinal research is needed to establish whether these deficits precede problem gambling, or develop in response to excessive gambling.

Behavioral Treatment

Behavioral treatments for PG include fellowships, such as Gamblers Anonymous (GA), and evidence-based psychotherapies such as cognitive behavioral therapy (CBT) and motivational interviewing. Below, the authors describe these therapies and provide some of the evidence for their effectiveness. For thorough reviews of the effectiveness of behavioral treatments for PG, the reader is referred to recent reviews (e.g., Gooding and Tarrier, 2009).

Gamblers Anonymous

GA is a mutual-help fellowship based on a 12-step model that is also the basis of other addiction fellowships including Alcoholics Anonymous and Narcotics Anonymous. Established in 1957, GA is the most frequently utilized intervention for PG in the United States, and chapters exist in many other countries (Petry, 2003).

Because the GA model is based on anonymity and mutual support rather than a therapist-driven treatment approach, study of the efficacy of GA is difficult. Consequently, there are few studies that examine the effectiveness of GA, but the few that do exist provide important information about the usefulness of this intervention. An early Scottish study followed individuals ($N = 232$) who attended at least one GA meeting to determine the extent to which they remained involved with the organization and engaged in recovery behaviors (Stewart and Brown, 1988). The study revealed that 22% of participants attended only one meeting, and 70% had stopped attending GA by their 10th meeting. Moreover, only 8% were abstinent from gambling a year after starting in GA and 7% were abstinent after 2 years.

Another study found more positive outcomes for GA, particularly when it is combined with professional treatment. This clinical trial, which included 342 pathological gamblers, reported that 48% of patients who attended treatment and GA concurrently abstained from gambling for at least 2 months, compared with 36% of those who only attended professional treatment (Petry, 2003). Thus, there may be some benefits of participating in GA for gambling abstinence. However, without randomized trials, one cannot rule out self-selection biases (e.g., greater motivation for treatment) as potential confounding factors that account for the apparent benefits of GA.

Cognitive and Cognitive-Behavioral Therapies

The most frequently studied treatments for PG include cognitive and CBT approaches. These treatments, consequently, also have the most empirical support for their efficacy. Cognitive and CBT approaches differ in that cognitive treatments focus primarily on gambling-related cognitive distortions such as biased memories about wins and losses, and illusion of control over gambling outcomes. CBT approaches, on the other hand, focus somewhat less on distortions, and place more emphasis on behavioral components including reinforcement of non-gambling behaviors, encouragement of problem solving, social skills building, and relapse prevention. In practice, the differences between cognitive and CBT treatments tend to be a matter of degree of emphasis rather than philosophical differences between these approaches. Thus, in this article, the authors refer to these approaches as 'CBT' regardless of whether the emphasis is more on cognitive or behavioral components.

Early studies by Ladouceur et al. revealed evidence for the efficacy of CBT approaches. In one study, participants ($N = 40$) were randomly assigned to twice-weekly (total 30 h) CBT or a wait-list control condition (Sylvain et al., 1997). Although the study experienced some retention issues ($n = 29$ were assessed at follow-up), 8 of 14 gamblers treated with CBT reported significant reductions in gambling severity compared with only 1 of 15 control participants.

Other research groups have similarly found beneficial effects of CBT for PG, and have also addressed some of the retention issues found in earlier studies. In one, 231 pathological gamblers were randomly assigned to one of three treatment

groups: referral to GA; GA referral plus a self-directed CBT manual; or GA referral plus eight sessions of individual CBT (Petry et al., 2006). CBT-treated participants exhibited better outcomes (reduced measures of problem gambling severity, frequency of gambling, and amount of money gambled) than did participants who only received a GA referral.

A number of other studies have found similarly positive outcomes of CBT for PG. Several thorough reviews have chronicled the efficacy of CBT approaches for PG. One meta-analysis examined published CBT clinical trials and found large effects for treatment outcome (e.g., abstinence from gambling) during treatment, as well as at 6-, 12-, and 24-month follow-up assessments (Goodling and Tarrier, 2009). Thus, the evidence for the efficacy of CBT for treating PG appears strong.

Motivational Enhancement and Brief Interventions

Brief interventions may be appropriate with problem and pathological gamblers who have less severe gambling problems, or who would otherwise not attend treatment. These interventions have often taken the form of a small number of therapy sessions (often 1–4) using brief advice about behavior change, or motivational enhancement therapy alone or in combination with CBT. In some cases, self-help manuals are employed as an adjunct to therapy.

In one study, problem gamblers ($N = 102$) were randomly assigned to one of three treatment conditions: (1) self-help workbook alone, (2) self-help workbook plus one motivational interview, or (3) wait-list (Hodgins et al., 2001). The workbook plus motivational interview treatment resulted in the greatest improvement in gambling symptoms. The workbook alone did not result in improvements in gambling symptoms compared to the waitlist condition. Another more recent study compared problem gamblers ($N = 314$) randomly assigned to receive (1) brief telephone motivational interview plus a self-help workbook, (2) brief motivational interview and workbook plus six booster telephone calls over a 9-month period, (3) workbook only, or (4) wait-list assignment (Hodgins et al., 2009). The two brief motivational interview conditions reported less gambling at 6 weeks and 6 months than those assigned to the workbook only and waitlist conditions. Booster calls did not appear to improve long-term outcomes.

Two other published brief intervention studies focused on motivational enhancement, CBT, and brief advice approaches (Petry et al., 2008, 2009). Both studies used a similar design, randomly assigning participants to one of four treatment conditions: (1) assessment only control, (2) 10 min of brief advice (to reduce gambling), (3) one 50-min session of motivational enhancement therapy (MET; based on the principles of motivational interviewing), or (4) one 50-min session of MET and three sessions of CBT. One study recruited problem gamblers from the community ($N = 180$) and found that brief advice resulted in significant reductions in gambling at the 6-week point and at 9 months. MET plus CBT significantly reduced gambling severity on one outcome measure (Addiction Severity Index Gambling score) between the 6-week and 9-month follow-up assessments, but MET alone did not result in significant changes compared with assessment only (Petry et al., 2008). The second study recruited problem gambling college students ($N = 117$) and revealed that the MET condition showed significant decreases in problem gambling severity over time compared with the assessment-only condition (Petry et al., 2009). Long-term benefits of MET for reducing gambling were also apparent at a 9-month follow-up. Brief advice and MET plus CBT also resulted in some positive gambling outcomes compared with assessment only. Taken together, these studies show that brief interventions can be effective in reducing gambling problems among gamblers for whom more intensive treatments are either not available or not wanted.

Medication Treatments

The most frequently studied pharmacological treatments for PG have been from three categories: (1) opioid antagonists, (2) antidepressants, and (3) mood stabilizers. To date, there are no medications that are approved by the American Food and Drug Administration (FDA) for treatment of PG. Thus, all medications prescribed for PG in the United States must be prescribed as off-label. Some of the research evidence for the efficacy of these medications is discussed below. The reader is referred to recent reviews for a more thorough summary of the cumulative evidence for medication efficacy (e.g., Pallesen et al., 2007).

Opioid Antagonists

Medications such as naltrexone and nalmefene hydrochloride are full opioid antagonists, and are typically used to treat opioid and alcohol dependence. There is evidence that addictive behaviors, such as gambling, may be associated with dysregulation of the mesolimbic dopamine system. Furthermore, endogenous opioids may serve to modulate dopamine release from the nucleus accumbens (Nacc). Modulation of the dopamine system may serve to reduce the excitement and urges associated with gambling for individuals with PG (Kim et al., 2001).

Several studies have examined the efficacy of opioid antagonists (most frequently naltrexone), and most have found that these medications reduce gambling symptoms and urges (see Pallsen et al., 2007). In one example of a double-blind, controlled study, participants with PG ($N = 83$) were randomly assigned to receive naltrexone (titrated to 250 mg) or placebo (Kim et al., 2001). Data analyzed from 45 participants who continued in the study past week six revealed that 75% of those who received naltrexone were 'much improved' or 'very much improved,' compared with only 24% of placebo-treated patients. Other double-blind trials have found similar results (e.g., Grant et al., 2008).

Antidepressant Medications

Selective serotonin reuptake inhibitors (SSRIs) and norepinephrine/dopamine reuptake inhibitors (NDRIs) that are typically used as treatments for major depression have been studied with gambling disordered individuals, in part because of the high rates of comorbidity between PG and depression, and also because of findings that suggest hypoactivation of 5-HT among problem gamblers (Moreno et al., 1991).

One meta-analysis of pharmacological interventions for PG found medications (opioid antagonists, antidepressants, and mood stabilizers) were generally effective at reducing problem gambling symptoms, and there were no differences in the effect sizes found for different medications (Pallesen et al., 2007). However, examination of individual controlled double-blind studies suggests that the effectiveness of antidepressant medications may be mediated by other factors including the specific medication used and characteristics of the patient population. For example, one double-blind study testing the effectiveness of paroxetine (an SSRI) among pathological gamblers ($N = 45$) revealed that it led to greater reductions in GD severity and gambling urges than did placebo (Kim et al., 2002). Another double-blind trial testing fluvoxamine (also an SSRI) against placebo ($N = 32$) showed that fluvoxamine did not result in significant benefits (Blanco et al., 2002). Similarly, a placebo-controlled, double-blind study of bupropion (an NDRI) for PG ($N = 39$) failed to find any significant improvements in GD symptoms relative to the control condition (Black et al., 2007). Thus, more study of antidepressants is needed to determine their efficacy in reducing gambling symptoms.

Other Medications

Mood stabilizers such as lithium have primarily been studied for treating PG among gamblers with concurrent bipolar disorder. A double-blind, placebo-controlled study of lithium carbonate for gambling among individuals with co-occurring PG and bipolar spectrum disorder ($N = 40$) revealed that lithium was associated with reduction in problem gambling symptoms, thoughts, and urges relative to placebo (Hollander et al., 2005) suggesting its potential efficacy in this population.

Glutamate is a neurotransmitter that has been linked to reward processes, and there is evidence that glutamate homeostatis imbalance may affect changes in corticostriatal neuroplasticity, which may impair communication between brain regions that are essential for processing rewards (e.g., Nacc and prefrontal cortex). Thus, there is some interest in pursuing medications that modulate glutamate in the brain. In the only open-label study conducted to date, 27 pathological gamblers were treated with *N*-acetyl cysteine (NAC), an amino acid that may enhance extracellular glutamate levels in the Nacc (Grant et al., 2007). In total, 60% of those treated with NAC were considered treatment responders. More rigorous, double-blind studies are needed to assess whether NAC is efficacious for treatment of PG, as well as whether other medications may be useful.

Non-Treatment-Assisted Recovery

Although there are several treatments that are efficacious for reducing PG severity, it is important to also acknowledge that the majority of individuals who recover from this disorder do so without the assistance of any intervention (Slutske, 2006). The largest study identified 206 lifetime pathological gamblers from two large household surveys and found that 36–39% (depending on the survey) reported having no past-year gambling problems despite the fact that only 7–10% of those surveyed had ever sought treatment (Slutske, 2006).

Summary

PG is a psychiatric disorder that affects 0.4–1.8% of the adult population across countries with legalized gambling, and frequently results in serious negative consequences including debt, bankruptcy, illegal behaviors, family and social conflict, and vocational/educational problems. PG is also associated with high rates of psychiatric and substance abuse comorbidities including relatively high rates of mood, anxiety, alcohol, drug use, and personality disorders, as well as elevated risk of suicidal ideation and attempt. PG was included in the DSM-IV as an Impulse Control Disorder Not Elsewhere Classified, but is now (as of May 2013) classified as an addictive disorder along with substance use disorders in the DSM-5, and has been renamed Gambling Disorder. Demographic factors, co-occurring psychopathology, and neurological vulnerabilities have been studied as potential risk factors of PG. GA is the most frequently utilized behavioral treatment for PG, but research evidence is the most abundant for CBT and motivational interviewing approaches at this time. Several medications have been examined in the treatment of gambling, but no medication has been approved by the FDA for this indication. Future research will be needed to ascertain the optimal treatment approaches for individuals suffering from gambling problems, but there is excellent support for some psychosocial interventions and growing support for some pharmacological ones.

Patient Adherence to Health Care Regimens

Abstract

A significant barrier to effective medical treatment involves patients' failure to follow treatment recommendations given by their health care provider, a term known as nonadherence (or noncompliance). More than 40% of patients take medications incorrectly, and almost 80% fail to follow dietary or exercise recommendations; some continue to engage in compromising health behaviors (e.g., smoking and alcohol abuse). Improving adherence depends upon effective communication between patients and providers, trust in the therapeutic relationship, and a realistic assessment of patients' knowledge and understanding of treatment. Such collaboration fosters improvements in health outcomes and reduces nonadherence.

Introduction

Nonadherence to prescribed medications and lifestyle treatments is an ever-present and complex problem that imposes a considerable economic burden upon modern health care systems (DiMatteo et al., 2012). Yearly U.S. expenditures for the consequences of patient nonadherence are estimated to be between 290 and 300 billion dollars (DiMatteo, 2004a; New England Healthcare Institute, 2009). Nonadherence can take many forms: treatment advice given to patients can be misunderstood, carried out incorrectly, forgotten, or completely ignored (Martin et al., 2005). Rates of treatment adherence vary widely across different diseases and treatment regimens, and can be extremely low even for treatments that are highly effective (DiMatteo et al., 2002; DiMatteo, 2004a; DiMatteo et al., 2007). For some long-term chronic medical conditions, adherence can be worse than 50% (DiMatteo, 2004a; Haskard-Zolnierek and DiMatteo, 2009). Moreover, nonadherence has been strongly associated with poor health outcomes, including more than 125,000 deaths each year (Christensen and Ehlers, 2002; Martin et al., 2005).

The medical literature on patient adherence is extensive, and continuous efforts to improve the relationship between adherence and treatment outcomes remain an ongoing challenge. Current research on the physician–patient relationship suggests that effective communication can enhance patient adherence through various mechanisms, including collaborative partnerships, provider empathy, and patient-centered communication (Haskard-Zolnierek and DiMatteo, 2009).

Patient nonadherence can be intentional or unintentional. 'Unintentional nonadherence' is used to describe situations in which patients incorrectly believe they are adherent, or try to be adherent but fail, whereas 'intentional nonadherence' describes the purposeful choice to dismiss treatment or change the regimen without consulting the provider (DiMatteo et al., 2012). Whether purposeful or accidental, nonadherence contributes to suboptimal health outcomes.

Adherence Terminology

Historically the term 'compliance' was first used to describe the behavior of following physicians' recommendations (Lutfey and Wishner, 1999; Vermeire et al., 2001; McNicholas, 2012). Recent studies have argued, however, that 'compliance' suggests an 'authoritative provider to submissive patient' model of care (Lutfey and Wishner, 1999). 'Adherence' has been proposed as a more accurate term that implies a physician–patient relationship based on collaborative partnerships and mutual respect (McNicholas, 2012). The shift in terminology reflects a fundamental change in the way health professionals view the process and delivery of care. Such change enables physicians to more accurately identify potential patient constraints (e.g., social and economic), and provides patients with more autonomy in managing their treatments (Lutfey and Wishner, 1999). The term 'adherence' further characterizes patients as independent individuals who pursue active and voluntary roles in efforts to achieve specific health goals.

Factors that Affect Patient Adherence

Adherence to medical treatment is a multifaceted process by which many factors influence the degree to which patients engage in disease management behaviors. Such factors include doubt about the expected benefits and efficacy of treatment (including side effects and perceived severity), and the unique demands of the treatment regimen itself (e.g., complex medication schedules) (DiMatteo et al., 2002; DiMatteo, 2004b; Martin et al., 2005). Socioeconomic factors, financial constraints (e.g., cost of medications), and patient characteristics can also negatively affect adherence. DiMatteo (2004b) found that the lack of social support strongly predicted patient nonadherence, in that adherence rates were 1.74 times higher in patients from cohesive families and 1.53 times lower in patients from families in conflict (DiMatteo, 2004b). Social support can benefit patients by helping them adjust and live with illness by buffering stress, influencing health behaviors, and changing patients' affective state (DiMatteo, 2004b).

In the following subsections, health literacy, the interpersonal dynamics of the physician–patient relationship, and depression will be discussed as major factors that affect patient adherence to medical treatment.

Health Literacy

The ability to adhere to medical directives requires patients' clear understating of their disease and treatment regimen. Health literacy involves the ability to obtain, process, and understand basic health information needed to make appropriate health decisions (Schillinger et al., 2003; Baker, 2006). The Institute of Medicine (2004) has estimated that more than 90 million people in the United States lack the necessary literacy skills needed to understand and act on health information given by their health care providers. Evidence to date suggests that limited health literacy negatively impacts health outcomes and decreases patient adherence (Gazmararian et al., 2003; Zaghloul and Goodfield, 2004). For example, in a study by Wagner et al. (2009), HIV patients with low health literacy had the highest rate of nonadherence, had less knowledge of their HIV treatment, and had lower self-efficacy for taking prescribed medications. Patients with low health literacy often use fewer preventive services, incur higher medical costs, have limited understanding of their treatment regimen, and have poorer health status (Gazmararian et al., 2003; Schillinger et al., 2003, 2004). Thus, low health literacy increases health disparities and negatively impacts patients' self-management and collaborative care (Schillinger et al., 2004).

While associations between health literacy and patient outcomes are evident, current literacy interventions aimed at improving adherence have shown inconsistent results (Wagner et al., 2009; Paasche-Orlow et al., 2006). Further research is needed to elucidate the underlying mechanisms in which health literacy influences health outcomes, including potential factors that may mediate or moderate the health literacy–adherence relationship.

Interpersonal Factors

The interpersonal dynamics of the physician–patient relationship are important factors that influence rates of adherence. For example, patients who feel that their physicians communicate well with them and actively encourage them to be involved in their own care are more motivated to adhere (O'Malley et al., 2002). Such agreement fosters a cohesive partnership and allows physicians and patients to work together toward a mutually agreed upon treatment plan (Jahng et al., 2005; Martin et al., 2005). In a meta-analysis conducted by Haskard-Zolnierek and DiMatteo (2009), researchers found that training physicians in communication skills resulted in significant improvements in patient adherence. The odds of patient adherence were 1.62 times higher for physicians who were trained in communication compared to the physicians who did not receive communication training (Haskard-Zolnierek and DiMatteo, 2009). Effective communication gives patients the opportunity to openly discuss the risks and benefits of recommended treatments and offers patients the ability to build rapport and trust in their physician, thus increasing disease management skills and ultimately improving adherence (Haskard-Zolnierek and DiMatteo, 2009).

Patients' trust in their physician is a crucial component of the physician–patient relationship. Some researchers suggest that trust has the largest effect on patient satisfaction and adherence to treatment (Shilling et al., 2003). Patients must believe that their physician is someone who can provide them with reliable and honest advice. O'Malley et al. (2002) found that adherence rates were three times higher in primary care relationships characterized by high levels of patient trust. Physicians who promote trust through collaborative partnerships and effective communication and who express compassion and 'bedside manner' for their patients, often succeed in fostering adherence and cooperation for a variety of treatments regimens (Martin et al., 2005).

Depression

Research to date suggests that one of the strongest predictors of nonadherence is patient depression. Depression has been cited as the most prevalent mental illness that physicians are called upon to treat and diagnose (Martin et al., 2005). Depression has been associated with devastating impairments equal to or greater than chronic diseases such as diabetes and hypertension (Hays et al., 1995; Wells and Sherbourne, 1999; Noël et al., 2004). Patients who are depressed experience pessimism and severe cognitive impairments in their daily functioning and often withdrawal from their social support, which diminishes their willingness and ability to follow health care directives (DiMatteo et al., 2000; Martin et al., 2005). DiMatteo et al. (2000) found that the odds of patient nonadherence to medical treatment were three times higher for depressed patients compared to nondepressed patients. Furthermore, researchers estimate that between 50 and 70% of patients with depression often go undiagnosed by primary care physicians (Martin et al., 2005). Recognizing depression as a risk factor for poor health outcomes fosters the potential for improvements in patients' commitment to care and can contribute to increases in subsequent adherence behaviors (DiMatteo et al., 2000).

Assessment of Patient Adherence

The delivery of effective medical care depends on the accurate assessment of patient adherence. Knowledge of patients' health behaviors can offer valuable insight into treatment efficacy and diagnosis (DiMatteo et al., 2013). No single method for the measurement of adherence has proven to be most effective; however, research does suggest that a multifaceted, personalized approach has the most potential for success (DiMatteo et al., 2012). The reasons for patient nonadherence are many, and the factors affecting the accuracy of patient reported adherence vary; thus, methods for improving the measurement of adherence must also vary (DiMatteo et al., 2013).

Patient adherence can be measured in a variety of ways depending on the disease or condition type (chronic or acute). Such methods include self-reports, patient diaries, collateral reports (reports by others), and pill counts. Electronic measures (e.g., medication event monitoring system) can also be used; however, such methods are quite expensive and often do not guarantee actual adherence behaviors. For example, the electronic event monitoring system (also known as MEMS) records the time and date of when patients open or remove medications from pillboxes; while such mechanisms can offer

reliable information, opening or removal of medication from MEMS systems do not necessarily mean that patients actually took their medications. Pharmacy refill assessment can be helpful, and direct observation can also be used to measure patient adherence. The latter, however, is difficult and costly (McNicholas, 2012). Direct observation is used in the treatments of infectious diseases like tuberculosis and HIV, where there are clear medical and economic advantages (McNicholas, 2012). Last, biological markers, using saliva or blood levels can also be an effective and accurate, although costly, way of assessing patient adherence. Thus, understanding patient adherence requires a multimethod approach, where multiple tools are used simultaneously to accurately identify how medical directives are being followed (DiMatteo et al., 2013).

Improving Patient Adherence

Improving patient adherence depends upon trust in the therapeutic relationship, and a realistic assessment of patients' knowledge and understanding of their treatment through effective physician–patient communication. Although the precise estimation of patient adherence is often elusive, physicians' full understanding of whether and why patients choose to adhere is essential (Martin et al., 2005). Moreover, nonadherence, despite its prevalence, often goes unrecognized (or is overestimated) by even the most clinically experienced health professionals (DiMatteo, 2004a; DiMatteo et al., 2012). As mentioned above, the accurate assessment of adherence depends largely on the development of a physician–patient relationship based on trust, where patients are able to admit difficulties in their ability to adhere without fear of criticism. When patients are given the opportunity to express their opinions in a nonthreatening environment, they are more likely to offer the most honest and accurate responses in regard to their treatment behaviors (Martin et al., 2005). From this, vital information about the patient can be obtained (e.g., patient attitudes and cultural beliefs, availability of social support, and any health or emotional challenges), allowing physicians to establish and further explore treatment options that are conducive to the specific needs of their patients.

Research to date suggests that there are numerous adherence-enhancing interventions; however, fewer than half have actually proven to be effective (McDonald et al., 2002; DiMatteo et al., 2012; McNicholas, 2012). Small changes, such as a simpler dosage of medication, may improve adherence. However, such small changes in complex treatment regimens may not be enough to achieve and maintain adherence over time (DiMatteo et al., 2012). As a result, no single intervention strategy can significantly improve adherence; instead a multifaceted approach offers the greatest opportunity for success.

Interventions that have successfully improved patient adherence have utilized a combination of patient education programs and structural support systems, such as patient reminders, increases in patients' clinical visits, or telephone calls from medical teams. Other interventions have incorporated the use of providing reinforcement or incentives, increasing patients' motivation, and providing counseling or family therapy and supportive care (McNicholas, 2012; Miller and DiMatteo, 2013). For example, patients with diabetes face many challenges in efforts to manage their chronic condition. In addition to patient education, continuous reinforcements, and long-term management are often required to maintain adherence over time (Norris et al., 2002). Additionally, several meta-analyses have targeted the importance of tailoring behavioral interventions to increase effectiveness. In Gibson et al. (2000), a review of 36 studies showed that training patients in asthma self-management reduced the risk of hospitalizations, and the number of medical visits and work days missed. Thus, adherence-enhancing interventions must be tailored to meet the unique needs of patients in order to obtain optimal effectiveness (DiMatteo et al., 2012).

Information-Motivation-Strategy Model

The elements of the *Information-Motivation-Strategy* (IMS) model (DiMatteo et al., 2012) offer health professionals the ability to assist patients in building effective disease management strategies to improve health outcomes and maximize treatment adherence overtime. The first component of the IMS model, *information*, outlines the importance of patients becoming more knowledgeable of their disease or treatment condition through effective provider–patient communication. Patients must be able to clearly understand their treatment recommendation in order to be adherent. The second component, *motivation*, highlights the importance of helping patients to believe in the potential efficacy of their recommended treatment and to make a commitment to follow it (Haskard-Zolnierek and DiMatteo, 2009). The final component, *strategy*, suggests that patients must be equipped with all the necessary resources to carry out their adherence behaviors. Providers and medical teams must be willing to help their patients overcome practical barriers that inhibit their ability to adhere (e.g., cost of medication and lack of transportation to scheduled appointments). Additionally, social support is a key element in patents' ability to adhere (DiMatteo, 2004a; DiMatteo et al., 2012). The IMS model offers physicians and health care professionals a practical heuristic that emphasizes the importance of targeting patient needs to promote and achieve optimal health outcomes.

Incentive-Based Engagement Strategies

Current research has explored incentives for physicians and other health professionals to counsel and monitor their patients for various health actions (e.g., smoking). Behavioral economic efforts that include incentive-based engagement strategies, informed collaborative choice, and health decision making, have the potential to help solve the most complex problems that underlie patient nonadherence. As discussed above, elements of the IMS model can be incorporated into provider counseling behaviors to influence patient adherence. As such, patients would be provided with *information*, encouraged to develop

individual *motivation*, and offered *strategies* to motivate and maintain (long-term) desired health habits through reinforcement (Martin et al., 2010).

The framework for incentive-based strategies offers some promise for the future of adherence-enhancing interventions. Worksite studies have already begun to examine incentive design, incentive value, communication strategies, and worksite culture in risk assessment participation. For example, in Volpp et al. (2008), a daily lottery, or financial incentive, demonstrated significant enhancements in patient adherence to medication use. Other incentive-based engagement strategies for various health behaviors, health outcomes, and patients populations have included value-based benefit design in health plans and electronic self-monitoring. In Martin et al. (2010), the results suggest that incentive-based strategies may be the first step in motivating patient adherence and engagement over time. However, further research is needed to determine the relative effects of various types of reinforcements and incentives, and their long-term effectiveness. A full understanding of the mechanisms that encourage health behaviors and the conditions that contribute to patient success will be required in order to implement these strategies in the most cost-effective ways (Volpp et al., 2008).

Conclusion

Patient adherence is essential for the success of quality health care outcomes. Provider–patient communication and the accurate assessment of adherence can increase patient satisfaction, improve overall quality of life, and ultimately reduce the risk of nonadherence. Nonadherence occurs for a variety of reasons, and depends upon the disease condition, the characteristics of the patient, and the type of treatment regimen. Providing patients with *information*, *motivation*, and helpful *strategies* can improve health outcomes and increase patient adherence. Behavioral economics approaches suggest that incentive-based strategies offer future advancements in the delivery of care. Incentive-based strategies can be used as a starting point to help motivate and move patients toward achieving long-term treatment goals (Martin et al., 2010).

Patron–Client Relations, Social and Anthropological Study of

Luis Roniger, Wake Forest University, Winston-Salem, NC, USA; Hebrew University of Jerusalem, Jerusalem, Israel

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Patron–client relations (PCR) involve asymmetric but mutually beneficial, open-ended transactions based on the differential control by individuals or groups over the access and flow of resources in stratified societies. Patrons provide selective access to resources they control, or place themselves or the clients in positions from which they can divert resources in their favor. In exchange, the clients are supposed to provide resources and services, while sometimes boosting the patron's reputation. The study of PCR has revealed the persisting impact of hierarchical networks in contemporary societies, contributing to the reevaluation of paradigms in social science. Debates continue about the institutional viability and significance of PCR and clientelism in late modernity.

Background

Patron–client relations (PCR) involve asymmetric but mutually beneficial, open-ended transactions based on the differential control by individuals or groups over the access and flow of resources in stratified societies. Whereas in antiquity, PCR formed part of the normative framework of society and could hardly be thought as conflicting with legal institutions and the social ethos, in modern societies PCR are built around such a conflict. While in principle and by law the clients have access to power centers and the ability to convert resources autonomously, they do not actualize this potential because it is neutralized by the patrons' control of the avenues to resource conversion and access to political centers. Yet, as in antiquity, mediation is projected into the institutional arena. Such mediation is contingent on the clients' entering into a relationship of exchange that necessarily limits the scope and convertibility of resources freely exchanged.

PCR originate in settings where social interaction is based on nonascriptive criteria and there are opportunities for mobility and yet there is structural inequality. Even though there are PCR in castelike and fully hierarchical societies, they are not a full-fledged phenomenon, as found in societies of the Mediterranean, Latin America, Southeast Asia, and the Middle East throughout the nineteenth to twenty-first centuries, and earlier on also in Western Europe. In such societies, PCR are motivated by the search for access to scarce resources, be they land, water sources, employment, a loan, schooling opportunities, or medical services. They may be rooted in the search for political protection, in bureaucrats providing preferential access to petitioners in return for future favors, in poor people sharing the social visibility of men or rank, while the latter use these links to consolidate their status. Professionals may seek prestige and a following of 'friends' and 'friends of friends' by offering services without demanding an immediate return. Union leaders, political activists, and government officials may use PCR to build networks of supporters, instrumental for gaining higher level positions, office, and control of institutional resources.

Terminology

The terms used by anthropology and the other social sciences to define such relationships originated in ancient Republican Rome, where relationships of *patrocinium* and *clientelae* proliferated during the Republic and into the Empire. These terms found their way into the vernaculars of Mediterranean and Latin American societies, whereas other terms are used for PCR elsewhere.

The Study of PCR

Expanding in the 1960s and 1970s, by the late 1970s and 1980s, it engaged in general and comparative analyses. In the 1990s, in-depth studies renewed interest in such phenomena in polities under transition to market economies and democracy, with a reevaluation of some of the premises of earlier approaches, especially regarding the connection between PCR and underdevelopment and their symbolic dimension. In the 2000s, the interest in PCR has been connected with the spread of research from anthropology to other social sciences, particularly political science and to a lesser extent sociology. From early dyadic emphases, research has increasingly revealed a more complex range of PCR analyzed in terms of networks, factions, and coalitions.

The study of PCR has been connected and contributed to analytical shifts in the social sciences, especially as it involved dealing with phenomena for which neither the group corporate model nor the paradigms anchored in the formal predicaments of modern institutions could provide a satisfactory guide. In parallel, research revealed the complexities of studying PCR, due to their informal character and to their cross-institutional insertion that requires interdisciplinary knowledge, bridging anthropology and sociology, political science and economics.

Increasingly, however, research has moved to normative assessments geared to eradicate PCR, often conflating it with corruption. In spite of several waves of research, the study of the conditions favoring or undermining clientelism is, perhaps surprisingly, still in its beginnings. Anthropological studies have provided great insight into the perspectives of politicians, brokers, voters, and others involved in PCR, yet their findings have been hard to generalize. Conversely, there are serious problems of reliability in the use of statistical proxies adopted by other social scientists, primarily political scientists, to establish to what extent a system is clientelistic. Given the informal and covert character of PCR, only systematic and long-term fieldwork can corroborate the reliability of the latter. One of the greatest challenges for future studies of PCR is to find

ways to integrate anthropological and sociological perspectives with approaches of economics and political science.

A Logic of Social Exchange

Research has identified a specific logic of social exchange and reciprocity beneath the wide gamut of PCR. Both the control of material and human resources and the presence of trust or its absence play a crucial role in it. This logic has been defined in the literature as *clientelism*. A related term is *patronage*, used interchangeably at times and alluding to the support granted by the patron to his followers and protégés.

The logic of clientelism involves a series of traits:

1. Hierarchy. Whereas friendship is an idiom of equality and similarity between human beings, PCR are built on an idiom of reciprocity and social exchange colored by various grades of inequality and hierarchy. (Although, in some cases, the latter are constrained by the potentially egalitarian images of individual self-fulfillment.)
2. The selective provision of benefits and resources to only limited segments of the population, in areas such as literacy, public health, defense, crime prevention, and infrastructure. Under such conditions, individuals and institutional actors are able to gather followings because they can dispense such access. They do so whether acting as *patrons* (in a strict sense), or as *brokers* with those who control the goods and services, or through a combination of both roles, in what has been called *patron brokerage*.
3. A relationship shaped according to the particular traits of the partners rather than on the basis of what they would be entitled to as members of social categories or in terms of formal institutional definition of roles.
4. PCR are characterized by the simultaneous exchange of two different types of resources and services: instrumental (e.g., economic and political) and 'sociational' or expressive (e.g., promises of loyalty). A package deal allowing for more than a restricted balanced, or market exchange is built-in within PCR, which has been identified as connected to generalized exchange. This determines expectations of entering more embracing attachments, often couched in terms of commitment, even though some PCR are very ambivalent in this respect. It brings agents to value or decry clientelism both as an instrumental means to a calculated end and for their own sake.
5. PCR are said to undermine group (i.e., class and strata) solidarity among both clients and patrons, especially among clients, and to exacerbate resentment and social antagonisms.
6. The favoritism involved implies that many people are excluded from PCR or are related to them only indirectly or intermittently. Where clientelism is highly valued, it generates 'inflationary' expectations that will be disappointed. This adds to the pressures exerted in PCR and to the fragility of clientelistic commitments, even where clientelism is a relatively persistent systemic trait.
7. PCR are neither fully contractual nor legal. They are based on informal, though tightly bound understandings. Most PCR are vulnerable to systemic pressures and to the changed contextual and market situation of the partners who can break them off accordingly.

These traits create an inherently contradictory situation, in which:

1. Asymmetrical power and inequality are combined with promises of solidarity.
2. Potential and/or actual coercion and exploitation coexist with an ideological emphasis on the voluntary character of the attachment on the one hand and on its obligatory nature on the other.
3. PCR structure of limiting payoffs can be only maintained by making payoffs.
4. The covered, informal, and unregulated character of PCR is used to project public claims over social resources and to bolster and propagate public images of power and reputation.
5. Even where clientelism is persistent, PCR are characterized by instability and by a perpetual contest, resource manipulation, and instability.

Exchange Strategies

The agent performing as client is not only expected to provide his patron with specific resources but must also accept the patron's control over his access – and that of other clients – to markets and public goods, and over his ability to convert resources fully. In a parallel manner, the patron's position is not as solid as it may seem, nor guaranteed, for instance by kinship or other ascriptive criteria. Although patrons invest much time and energy in gaining and retaining control over clients, their control is never fully legitimized. It is vulnerable to attack by social forces committed to formal, universalistic principles of social organization and exchange, by the competition of other patrons and brokers, potential and actual, and by social forces excluded from clientelistic relations. Owing to these constant threats, patrons are compelled to rely on their followers to solidify their position. The patron must also relinquish some of the short-term material gains that might accrue from a position of preeminence in order to earn the right to determine the basic rules of the social relationships. In return, the client is protected from social or material insecurity, and is provided with goods, services, and social advancement. Certain types of trust (focalized rather than generalized) are associated with such dynamics.

Complementary exchange strategies are built, which signal what Vincent Lemieux defined as a 'double transformation.' That is, an abdication of autonomy on the client's part and a relaxation of hierarchical controls on the patron's part, through which the client's lack of power becomes dominated power and the latter's lack of domination becomes dominating authority. These exchange strategies are not only affected by immediate, mostly technical considerations of power and instrumentality, but also often encompass mutual, relatively long-term, compromises based on commitments as the prerequisite for the maintenance of ongoing social relationships.

The Context of PCR

The contradictions and instability inherent in PCR and clientelism are symptomatic of the macrosocial context in which they arise. Unlike societies in which hereditary ascriptive principles predominate, full-fledged clientelism flourishes

where markets are no longer controlled through primordial units and allow for an open flow of resources and opportunities for mobility. (This is what distinguishes clientelism from *feudalism*, as pointed out already by Max Weber in *Economy and Society* (vol. II, chapters 12–13) and later on by historians of European nations.) This trend, however, goes hand in hand with a strong tendency toward unequal access to markets and sociopolitical spheres. As they affect distribution and redistribution, clientelism and PCR remain subject to the dynamics of the political economy. Marketing economies, accelerated urbanization, and the expansion or reduction of state administrations affect PCR. Research has shown that the spread of market forces and/or the establishment of forceful administrations eroded patrimonial patterns of social exchange in rural Third World settings, making the terms of trade increasingly oppressive for rural clienteles. Similarly, the impact of world economic trends, fluctuations in the international price of commodities, the complexity of international trade, banking, and aid affected the pool of patronage resources available to states and other agencies, and influenced patterns of control, distribution, and redistribution. Moreover, as these arrangements are not fully legitimized, they remain vulnerable to the challenge of countervailing social forces.

The Comparative Analysis of PCR

Until the early 1980s, it was dominated by the contrast between traditional dyadic patronage and modern party-directed clientelism, a distinction that derived from the dominant paradigm of modernization. This contrast was made classic by Alex Weingrod, who traced it in the different terminology of anthropology and political science and related it to the degree of segmentation or integration of local sectors within nation-states. A clear-cut developmental emphasis was identified as effecting greater network complexity and eroding the seemingly personalized and intimate relationships of traditional settings. This approach focused almost exclusively on the organizational differences of PCR, deriving other aspects from them in a functionalist manner.

In the 1980s and 1990s, comparative analysis has moved away toward approaches that pay attention also to other aspects of PCR. Greater attention was paid first to the modes of agents' role making. Second, the styles of setting a relationship were studied, following what Robert Paine very early on called a generative transactional model of patronage. Third, symbolic and discursive elements, including images and trust, were analyzed as important for the development of PCR. Fourth, the fundamental distinction between PCR as an *addendum* to the core institutional framework in most human societies and clientelism as a strategy of social exchange at the core of institutional life in certain societies and periods. And last but not the least, the issues related to the institutional viability of PCR under democratization, liberalization, and institutional change of late modernity.

Debates on Institutional Viability

Researchers have differed in their interpretation of the institutional viability and significance of PCR in late modern settings. From one perspective, PCR have been analyzed as neutralizing the system of representation and general entitlements, by placing 'friends' in the strategic positions of power and control. Clienteles have been depicted as inimical to the institutionalization of public accountability and therefore stand in contradistinction to a politics open to generalization and participation, and to a discourse aimed at the protection of individual and collective rights. Others have emphasized the pragmatics of social action, stressing that PCR have been an important mechanism for obtaining transactional benefits, in resource allocation and in providing local–regional–national mechanisms of interrelation and integration. While PCR run counter to universalistic standards, they are sensitive to local sentiment, instrumental for solving problems, and provide ways of incorporating new sectors of the population such as immigrants and of advancing political actors with an entrepreneurial ability. From this perspective, it is claimed that as long as clienteles maintain some balance of reciprocity, the participation in political and economic markets by the 'capi-clientele' (to borrow Gaetano Mosca's expression) – be he or she a broker, a patron or a patron–broker – constitutes a means for individuals in their entourage to influence public decisions. In this sense, the literature alludes to PCR as reconciling public and private authority and formal and informal rules of the game.

PCR may be resented, criticized, and opposed by social forces and coalitions wishing to curtail its presence alongside bureaucratic universalism and market rationality. In parallel, sectors benefiting from patronage may see it as a pragmatic avenue of controlled freedom, useful for advancing in social, economic, and political domains that are regulated by competition for access to power, resources, and services. This duality reflects a major tension of modern democratic polities. As part of the Western political tradition, modern democracies are built on citizenship that implies political equality but leaves the economic domain open to inequalities.

This explains the paradoxical development of clientelistic networks in societies that have adopted policies of macroeconomic adjustment and restructuring. Promotion of liberalization, reduction of state intervention in favor of market mechanisms, privatization of state-owned and state-supported services, and curtailment of union power further fragment society and heighten the need for support networks. When available, clientelism has remained as important as ever throughout political revamping in Poland, Russia, Hungary, Romania, Brazil, Argentina, and Turkey.

In centralized polities, PCR have been depicted as a 'lubricant' to bypass the inefficient and rigid official system, constituting highly trusted informal problem-solving networks that provide instrumental advantages and emotional support in situations of low institutional trust. In representative democracies, clientelism has been sometimes highly effective in encouraging and rewarding party activists and in molding incumbency to public offices in accordance with politically sensitive stances. Clientelism continues to be useful in the competition for power and, once power is achieved, for effectively formulating and implementing policies. Within such a framework, patronage has become a restricted but legitimate procedure related to the acknowledged right of high office incumbents to appoint their followers to positions of public responsibility. In other respects, clientelism remains

controversial and is open to allegations of corruption, due to its informal, unregulated character, and the particularistic use of public resources. In other situations, it is ignored as long as possible or is disguised as friendship, which is more acceptable in terms of the proclaimed ethos of modern equality.

Contemporary studies suggest that in the environment of postindustrial societies, patronage develop among professional and upper strata, rather than being a phenomenon restricted to the lower classes. In addition, PCR are not confined to politics in the narrow sense, but proliferate as well in the arts, the academia, the church, the media, and even in business – whenever we are dealing with the power of appointment and the granting of access to benefits, goods, services, influence, and honors.

Changes in the perception of PCR are of systemic consequence if they result in the institutionalization of mechanisms through which citizens can press for their rights and entitlements without personal mediation. Such changes include: civil service reforms, nonpartisan public systems, recognized charters of rights, controls over party fund raising, and nonpartisan comptrollers as a prestigious and trustworthy branch of government. The functioning of these institutional mechanisms hinge on public support for a configuration of the public sphere structured around public accountability and formal responsiveness to turn more and more discrete issues into publicly negotiable and politically consequential.

Abstract

Ivan Petrovich Pavlov is recognized as one of the most renowned of Russian scientists. He was born in 1849 in a small Russian village and attended the local ecclesiastical schools. However, he was heavily influenced by Darwin, as well as the famous Russian physiologist Sechenov and entered St. Petersburg State University to study physiology. He received a medical diploma in 1879 and successfully defended his doctoral dissertation in 1883. Pavlov later became the Chair of the Physiology Department at the Military Medical Academy and Head of the Department of Physiology in the Institute of Experimental Medicine. He received the Nobel Prize in 1905 for his work on the nervous control of the digestive system by its autonomic input. Early in the twentieth century Pavlov's work changed to the study of conditioned reflexes, using salivation as the conditioned response. Pavlov was able to demonstrate in an objective manner through the development of a salivary fistula that salivation could be elicited not only by food but also by neutral stimuli that came to be associated with feeding. The use of these conditioned reflex techniques has come to be one of the major methods used in studying brain-behavior relationships in modern psychology.

Ivan Petrovich Pavlov is recognized as one of the most renowned of Russian scientists and is clearly the best known Russian physiologist of his era. His work on the physiology of the digestive system was well respected by his colleagues worldwide during his lifetime. This respect earned him the first Nobel Prize awarded to a physiologist and the first to a Russian scientist in 1905. Although the excellence of his work on the physiology of the digestive system is well recognized, Pavlov is even better known for his investigations into what he termed 'conditioned reflexes.' This work has had a worldwide impact on the fields of learning and memory, psychology, neuroscience, etc. Pavlov's life can be divided roughly into three phases. The first, including his early years, was a phase in which Pavlov received his early training in physiology and medicine. A second investigational phase was one in which his work on the physiology of the digestive system was done. The third includes his work, for which he became most famous, on conditioned reflexes.

Pavlov's Early Life

Ivan Petrovich Pavlov was born on 14 September 1849, in the small town of Ryazan, about 100 miles southeast of Moscow. He was the eldest of five children. His father was a priest in one of the poorer parishes. Thus, during Pavlov's early life he lived in extreme poverty. Nevertheless, the life of Pavlov and his siblings was apparently intellectually rich and their father instilled a love of learning in each of his children. Pavlov entered the ecclesiastical high school of Ryazan, and from there to the local seminary, obstentially to pursue an ecclesiastical career, as his father and other members of his family had done. Pavlov thus entered school during the Russian Cultural Revolution of the 1860s and therefore was exposed to the leaders of this revolution, such as Turgeanyev, Doskovsky, Tolstoy, etc. However, he was apparently most heavily influenced by Pisarev, from whom he learned of Darwin's theory of natural selection and the famous Russian physiologist Sechenov, who had just published *Reflexes of the Brain* in 1896. It is clear that these kinds of influences on Pavlov steered him in the direction of science and consequently he left the ecclesiastical seminary and entered the Mathematics–Physics Department at St. Petersburg State University.

In 1875 Pavlov graduated from the University with a degree in natural sciences. However, due to his interest in physiology he started work as an assistant in the Department of Physiology in the Medical Surgery Academy (now the Military Medical Academy) and in 1879 received a medical diploma. He was then recommended for an appointment with Andre Botkin, who was the most renowned clinician in St. Petersburg at the time. Botkin assigned Pavlov the task of heading his recently established experimental research laboratory. Since Botkin had little interest in experimental work, Pavlov was able to work pretty much independently on problems of his choice. He worked here until 1890. He was heavily influenced by Botkin's theories on the role that the nervous system plays in the regulation of physiological function, and it was here that Pavlov began his studies of the peripheral nerves of the heart and where in 1883 he successfully defended his doctoral dissertation in this area.

During this period of time he also became acquainted with a small circle of friends including another university student, Seraphima Vasilievna, who was in her last year at the Pedagogical Institute. They were married in 1881. During the first years of their married life they lived in extreme poverty. After a first miscarriage, Seraphima gave birth to a son but he also died the next summer. They did, however, later have four children (three boys and a girl) and, based on Seraphima's memoirs published after Pavlov's death, apparently enjoyed a happy family life. In 1883 Pavlov spent 2 years working abroad in the laboratories of Heidenhain and Ludwig in Germany. On his return to St. Petersburg, he resumed his work in Botkin's laboratory and in 1890 was appointed Professor in the Pharmacology Department at the Military Medical Academy. Five years later he joined the Physiology Department there, which he headed for the rest of his career. He was also later appointed the Head of the Department of Physiology in the newly established Institute of Experimental Medicine. Pavlov

worked in his laboratory there until his death at the age of 87 in Leningrad on 27 February 1936.

Pavlov's Work on the Digestive System

Pavlov did most of his research on the physiology of digestion during his early years at the Institute for Experimental Medicine. Here he was able to develop his surgical skills with chronic experiments, which he advocated over the acute experiments that were typically done in physiology at that time. Pavlov believed that the study of the entire organism in as normal a state as possible was crucial to understanding physiological systems. Moreover, he was an excellent surgeon and became quite experienced in developing surgical procedures that allowed his dogs to fully recover. In such animals the digestive processes could be studied under normal conditions. As a consequence of this approach to physiology he developed a 'stomach pouch,' which involves isolating a portion of the dog's stomach, so that it can be directly observed by the experimenter. Unlike previous researchers, the nervous input to the isolated portion of the stomach was intact in the 'Pavlov Pouch.' Using this preparation Pavlov could observe the digestive juices and enzymes that occurred as a result of normal food intake, or after direct placement of food into the stomach. It was the comparison of these two states which led to Pavlov's interesting discovery that food placed in the mouth as a normal consequence of eating, produced a significantly larger amount of gastric secretion than when food was placed directly in the stomach. Moreover, when animals were sham fed, viz. when the normal intake of food through the mouth was allowed to take place but the food was diverted externally, a significant amount of gastric secretion occurred, even though the food never reached the stomach.

It was these types of experiments, which led to Pavlov's pioneering discoveries regarding the control of the digestive system by its autonomic nervous input, primarily the vagus nerve. He showed for example that a major consequence of this neural control involves both gastric and pancreatic secretions before any food actually reaches the stomach, by the sight of the food bowl for example, or other stimuli previously associated with eating. These 'psychic secretions' turned out to be of great importance for digestion and led to Pavlov's major conclusions regarding what came to be known as the doctrine of nervism, in which the major tenet states that the physiological control of bodily systems is primarily through its nervous input. This work culminated in the publication of *Lectures on the Work of the Digestive Glands* in 1897, later translated into English in 1910 (Pavlov, 1910). However, it was during this same period of time that two British physiologists, W. Bayliss and E.J. Starling, demonstrated that the secretin of the pancreatic enzymes was primarily due to release of a substance by the intestines during eating, which came to be called secretion. These investigators thus claimed that the doctrine of nervism was invalidated by their discoveries. However, as is typically the case with two opposing theories of biological function, both experimental outcomes were eventually confirmed. The new science of neuroendocrinology thus came to be established, and it is now widely accepted that nervous control over hormonal output is a ubiquitous aspect of physiological function.

Pavlov's Work on Conditioned Reflexes

As a result of his work on the digestive processes, as noted above, Pavlov also observed that nonfood stimuli that became associated with food were able to elicit salivary secretions, and to a lesser extent digestive secretions, even though no food was actually present in the mouth. These 'psychic secretions' came to form the basis for the remainder of Pavlov's work and resulted in his experiments moving in a new direction, which caused an almost complete cessation of work on the digestive system proper. However, Pavlov believed that by studying 'psychic secretions,' which he referred to as 'conditioned reflexes,' he would be able to demonstrate in an objective manner how the brain controls adaptive behaviors. Pavlov developed a salivary fistula, similar to the stomach pouch, in which the release of salivation in the mouth was directed through a tube to a container outside the mouth. Through this technique he was able to discover the amount and kinds of salivary secretions that were produced by different kinds of sensory stimuli.

Using these techniques Pavlov began the study of a new kind of learning, which has come to be known as 'classical' or 'Pavlovian' conditioning. Classical conditioning occurs whenever a neutral stimulus acts as a signal for a forthcoming significant event. Thus, for example, in one of Pavlov's original experiments a pure tone, a metronome, or some other equally neutral stimulus signaled to a dog that it was about to receive an appetitive stimulus, i.e., meat powder (see Pavlov, 1927). In Pavlov's experiments this neutral auditory stimulus was termed the conditioned stimulus (CS) and the meat powder the unconditioned stimulus (UnS). The UnS always elicits what Pavlov referred to as an unconditioned response (UR), viz. salivation in response to the meat powder. The behavior in which Pavlov became most interested, however, was not increased salivation in response to the meat powder, which he had previously studied intensively, but the new learned response to the neutral CS. This response also consisted of salivation, but in this case salivation in response to the initial neutral auditory stimulus, which resulted from its consistently preceding the meat powder over many CS/UnS presentations. This new learned response was referred to as a conditioned response (CR) and was thought to be only temporary and required reinforcement by the UnS for its maintenance. The UnS is thus often referred to as a reinforcer, since it reinforces the new response to the CS.

It should be noted that the CR does not, however, always resemble the UR as is the case with the original salivation experiments, which Pavlov reported. Indeed often the CR appears to be opposite to the UR. For example, the autonomic changes associated with the contextual cues that signal drug administration, an often-studied type of classical conditioning, are opposite in direction to those produced by the drug itself (Siegel, 1979) and the heart rate CR to CSs that signal aversive UnSs consist of bradycardia, whereas the UR to these same aversive stimuli alone consists of tachycardia. There are many other experimental operations that have been studied since the time of Pavlov, which produce similar new responses to an original neutral stimulus that is always followed by either a noxious or appetitive event. Pavlov thus developed a new

experimental methodology for studying the role of the brain as it initiates new behaviors enabling animals to adapt to their environmental circumstances.

One of Pavlov's greatest contributions to physiology was to emphasize that the nature of the 'psychic secretions,' which were previously thought to be in the realm of psychology, could be objectively studied by physiologists through the conditioned reflex method. He thus believed that the true road to understanding brain function and therefore human behavior was through the objective physiological techniques, which he had developed. In fact Pavlov went on to consider a range of higher level functions such as thinking, reading, emotional reactivity, etc., in terms of conditioned reflexes. Using the ideas of cortical excitation and inhibition, which he studied extensively using the conditioned reflex methodology, he was thus able to explain many complicated behavioral phenomena, such as the neuroses and other psychiatric disturbances. Although Pavlov's influence on experimental psychology has been extensive and dramatic, as detailed in Section Pavlov's Influence on Modern Psychology, many of the details of his theoretical interpretations have since been found to be lacking. Nevertheless the basic operational procedures for determining the effects of a signal on brain processing has been extremely influential in studying brain function.

Pavlov's Influence on Modern Psychology

During his lifetime and immediately thereafter, Pavlov had a tremendous influence on physiology and the study of brain function. Many students were drawn to his laboratory during the early part of the twentieth century to study the basic laws governing the activity of the brain, and during this period of time Pavlov received worldwide acclaim and recognition. Pavlov's work was little affected by the Russian Revolution, which was also ongoing during this time. He maintained a skeptical attitude regarding politics and government, but nevertheless his worldwide recognition led the Communists to continue to fund his research at high levels. Thus, the Soviet Union became known for its support of the study of physiology, and it was during this time that a great center for the study of physiology with many distinguished workers was developed in the Soviet Union, primarily under Pavlov's leadership.

It was his influence outside the Soviet Union, however, that resulted in Pavlov's most notable successes in science, primarily in the field of psychology, which Pavlov had previously rejected. Thus the conditioned reflex methodology was instrumental to the development of the behavioristic movement in psychology in the early part of the twentieth century. John Broadus Watson, one of the major pioneers in the development of behaviorism, utilized the conditioned reflex methodology to explain the entire subject field of psychology, which consisted, according to behaviorists, in the study of overt behavior without reference to subjective phenomena such as cognitions, learning, feelings, etc. The publication of *Psychology as the Behaviorist Views It* (1913) by Watson thus became instrumental in informing American and English scientists of Pavlov's work. The translation of Pavlov's *Conditioned Reflexes* (1927) by Anrep made his work available to English speaking scientists. As a result, experimental psychologists began to explore the new conditioned reflex methods for studying behavior at several academic centers in the USA. As was noted by Babkin (1949), however, much of the work done by the American researchers focused on skeletal reflexes, as opposed to the visceral reflexes, to which Pavlov and his students had previously devoted most of their work.

One of the basic experiments developed by American psychologists was the classical eyeblink-conditioning paradigm. Using this methodology human or animal subjects are presented with a corneal airpuff, which causes reflexive closure of the eyelids. However, when this unconditioned stimulus is preceded by a conditioned stimulus such as a light or pure tone, eventually subjects began to show anticipatory eyeblinks during the conditioned stimulus, which occur even though the corneal airpuff is not presented. This paradigm came to be used extensively in the early 1940s and 1950s as behaviorism began to gather momentum. Its success in the hands of the American psychologists led to the de-emphasis on visceral changes as conditioned responses in the USA. However, Horsley Gantt, who had previously studied with Pavlov, demonstrated in his Johns Hopkins laboratory that both visceral and skeletal responses could be studied in the same organisms, and that the two responses differed greatly in their acquisition and the conditioning parameters required to elicit learning (Gantt, 1960). Much of this early work on classical conditioning was, however, overshadowed by the emphasis given to operant conditioning by other behaviorists, such as B.F. Skinner and Clark Hull. Thus, it was only during the early 1960s that classical conditioning became a popular technique for studying behavior. This was due to the development by I. Gormezano of the classically conditioned nictitating membrane response in the rabbit (Gormezano, 1966). The nictitating membrane is a third laterally moving eyelid found in the rabbit and some other mammals (e.g., cat). Using this animal preparation Gormezano and his students were able to demonstrate the parametric circumstances under which this kind of learning takes place and what kinds of visceral changes accompany them, e.g., conditioned changes in heart rate, blood pressure, etc. The popularity of this technique became even greater when integrated with the simultaneously developing field of behavioral neuroscience. Classical conditioning offers several advantages for studying concomitant brain function as well as new learned behaviors. For example, concomitant electrophysiological recording from single neurons in specific parts of the brain have led to the discovery that different brain structures are involved in visceral vs skeletal learning (Thompson, 1991). Moreover, more recent brain scanning techniques in humans have demonstrated that even during simple classical eyeblink conditioning activation of several specific areas of the brain, which are known to be involved in learning and memory processes, occurs (e.g., Blaxton et al., 1996).

Thus the use of the conditioned reflex techniques originally developed by Pavlov has come to be one of the major methods used in studying brain-behavior relationships in modern psychology. Pavlov's contribution to this new technology was at a basic level and much of his earlier conclusions regarding the results of his manipulations were, of course, erroneous.

However, his contributions we now know were instrumental to the development of modern psychology.

Abstract

Pay-for-performance stands for a variety of compensation practices that are designed to reinforce past performance and encourage future performance. The purpose of this article is to review some of the more important issues pertaining to pay-for-performance concepts and research. First, pay-for-performance concepts and practices are introduced in the context of total compensation practices. Second, consideration is given to a longstanding vexing concern about whether rewarding performance with tangible rewards may actually undermine performance. Third, job performance constructs in the context of pay-for-performance are considered. Fourth, executive compensation determination and its implications for pay-for-performance are reviewed. Finally, the importance of recognizing national culture in pay-for-performance research is addressed.

The pay-for-performance topic is ubiquitous throughout all types of organizations. In recent decades, the role of pay-for-performance was expanding beyond some of the traditional topics that have driven past psychological research. Questions such as 'Are alternative pay-for-performance plans equally effective in influencing employee motivation and job performance?' were the focus. Increasingly the term pay-for-performance was being used to convey a much broader and very different set of activities than it once did. For instance, researchers are asking questions such as 'Are executives paid commensurately with organizational performance such as changes in stock prices?' Whereas traditional research focused largely on rank-and-file and managerial employee categories, more recent research has focused on the chief executive officers. The former question fits with traditional pay-for-performance research that has been based in psychological theories of motivation; the latter represents a more contemporary approach of compensation practices in a business strategy context, often referred to as executive compensation that has been largely based on theories in economics, finance, and sociology.

Compensation represents both the intrinsic and extrinsic rewards employees receive for performing their jobs (Martocchio, 2015). Together, both intrinsic and extrinsic compensation describe an organization's total compensation. In practice, organizations pay employees to perform the jobs for which they were hired. By the end of 2013, the US private sector labor force totaled, approximately 115 million individuals and the costs of pay, wages, and salaries have increased dramatically in recent years ($20.55 in hourly wages, which increased 3.8% in an 18-month period through late 2013). It would seem reasonable, then, to expect there to be a strong continuing stream of research on topics such as pay-for-performance to better understand how increasing wage and salary costs relate to employee productivity. However, this has not been the case.

According to Gupta and Shaw (2014), of more than 1200 sessions at the 2013 annual meetings of the Society for Industrial and Organizational Psychology, only three are related to compensation, rewards, or benefits. Similarly, the program of the HR division of the Academy of Management featured only three sessions on compensation, among hundreds devoted to other topics, at the 2012 annual meetings. In addition, they cited an analysis which revealed that of 111 articles published in *Personnel Psychology* in 2003–07, only two focused on compensation issues; the parallel proportion was seven of 457 in *Journal of Applied Psychology* (Cascio and Aguinis, 2008). For the period 2008–13, only three additional articles on employee compensation were published in the *Journal of Applied Psychology* (of 602 total articles published in this period) and one article on employee compensation was published in *Personnel Psychology* (of 153 articles). Research on executive compensation is plentiful, and it appears in scholarly journals that publish strategic management research, including *Academy of Management Journal*, *Journal of Management*, and *Strategic Management Journal*.

Compensation Components

Compensation represents both the intrinsic and extrinsic (monetary) rewards or returns employees receive for performing their jobs, and compensation professionals typically refer to both types of compensation as total compensation (Martocchio, 2015). Intangible compensation includes recognition, status, employment security, challenging work, and unplanned learning opportunities. Tangible rewards include pay (hourly wage or annual or annual salary) and employee benefits (such as paid time-off). Whereas organizational development professionals promote intrinsic compensation primarily through effective job design and employee feedback mechanisms, compensation professionals are responsible for extrinsic compensation.

Intrinsic Compensation

Intrinsic compensation represents employees' critical psychological states (that is, intrinsic motivation) that result from performing their jobs. Job characteristics theory (Hackman and Oldham, 1976) describes these critical psychological states. According to this job theory, employees experience enhanced psychological states (that is, intrinsic compensation) when

their jobs rate high on five core job dimensions: skill variety, task identity, task significance, autonomy, and feedback.

Extrinsic Compensation

Extrinsic compensation includes both pay and employee benefits. Employees receive base pay, or money, for performing their jobs. Base pay is recurring; that is, employees continue to receive base pay as long as they remain in their jobs. Organizations disburse base pay to employees as hourly pay or (wage) as an annual salary. Employees earn hourly pay for each hour worked. They earn salaries for performing their jobs, regardless of the actual number of hours worked. Organizations measure salary on an annual basis. The Fair Labor Standards Act established criteria for determining whether employees should be paid on an hourly or salary basis for the purposes of determining who qualifies for overtime pay when working longer than the standard work week. In general, managerial, professional, and executive-level jobs are exempt from the overtime pay provision while most other jobs are not exempt.

In either case, most organizations implement pay-for-performance plans to determine whether pay increases should be awarded, and, if so, by how much. Organizations embrace the importance of capital, which refers to the factors that enable themselves to generate income and economic value. Human capital (Becker, 1975), as defined by economists, refer to sets of collective skills, knowledge, and ability that employees can apply to create economic value for their employers. There are a variety of different types of capital that organizations rely on to create value, including financial capital (cash) and capital equipment (state-of-the-art robotics used in manufacturing). Unlike other forms of capital, employers cannot own human capital. Organizations purchase the use of human capital by paying employees an hourly wage, salary, or bonuses and providing benefits such as paid vacation and health insurance. Also, organizations help develop human capital to their advantage by offering training programs aimed at further boosting employee productivity, and rewarding better performance increases with boosts to pay.

Pay-for-Performance

Merit pay and incentive pay are the primary mechanisms for providing performance-based pay. The intent of pay-for-performance plans is to reward excellent job performance, motivate future performance, and help employers retain valued employees. Under *merit pay*, employees earn permanent increases to base pay according to their performance. Most often, an employee's supervisor or manager provides an evaluation of past performance (oftentimes for periods ranging between 6 months and 1 year) based on subjective judgment. The amount of a merit pay increase should reflect prior job performance levels according to the performance evaluation judgment and the amount ideally motivate employees toward striving for exemplary performance. The pay raise amount should be meaningful to employees in an absolute and relative sense. In an absolute sense, the concept of just-meaningful pay increase refers to the minimum pay increase that employees will see as making a meaningful change in compensation (Krefting and Mahoney, 1977). The basic premise of this concept is that a trivial pay increase for average or better employees is not likely to reinforce their performance or to motivate enhanced future performance. Equity theory (Adams, 1963) tells us that individuals who judge that their pay or pay increases are commensurate with their inputs such as effort, skills, and knowledge that manifest in job performance, relative to the pay or pay increases of comparison others (coworkers) who perform similar or identical jobs. Perceptions of underpayment inequity (Adams, 1965) may intensify because budget reductions make it more challenging to recognize differences in employee performance. Exemplary performers may receive pay raises that are only slightly higher than average performers. Also, overall lower pay increases may fall below the threshold of just-meaningful pay differences (Zedeck and Smith, 1968), then, possibly exacerbating perceptions of inequity.

Incentive pay is defined as compensation (other than base wages or salaries) that fluctuates according to employees' attainment of some standard based on a *preestablished* formula, individual or group goals, or organization earnings. Incentive pay or variable pay rewards employees for partially or completely attaining a predetermined work objective based on objective criteria such as sales volume, safety records, and team performance such as manufacturing quality.

Effective incentive pay systems are based on three assumptions. First, individual employees and work teams differ in how much they contribute to the organization, both in what they do as well as in how well they do it. Second, the organization's overall performance depends to a large degree on the performance of individuals and groups within the organization. Third, to attract, retain, and motivate high performers and to be fair to all employees, an organization needs to reward employees on the basis of their relative performance.

Goal setting is a motivational technique that involves employees' participation in setting precise job performance goals for themselves. Locke (1968) first established the theoretical basis for how goal setting can impact motivation. Latham and Yukl (1975) reviewed a multitude of goal setting research from which they created a theoretical framework for how goal setting should be used in organizations to motivate employee performance. Rewards are those tangible things (pay, benefits, recognition, promotion opportunities, and so forth) that an organization provides to its employees in return for their performance.

Incentive pay augments employees' base pay, but incentive pay appears as one-time payments. Employees usually receive a combination of recurring base pay and incentive pay, with base pay representing the greater portion of monetary compensation. More employees are presently eligible for incentive pay than ever before, as organizations seek to control costs and motivate employees continually to strive for exemplary performance.

Is Monetary Compensation a Nonstarter for Discussing Employee Performance?

Notwithstanding the ubiquity of pay-for-performance practices, a body of literature has given pause to speculate whether pay may diminish performance. Cognitive evaluation theory

(CET) maintains that pay is likely to reduce an individual's interest in the job at hand. Consequently, reduced intrinsic motivation may be more likely to diminish job performance.

At center stage is the concept of intrinsic motivation. Deci and Ryan (1985) describe intrinsic motivation as "based in the innate, organismic needs for competence and self-determination" (p. 33), and argue that it occurs in its purest form when "a person does an activity in the absence of a reward contingency or control" (p. 35). In the CET framework, pay undercuts intrinsic motivation because it exerts a governing quality. Employers expect employees to work diligently when on the job. In rare instances, employees do have the freedom not to perform their jobs whenever they desire if they expect to be paid. For most, pay provides for basic needs including food and shelter without which individuals would not survive. According to Rynes et al. (2005), this perception of being controlled is assumed to be "demotivational" and to work against the potential incentive effects of extrinsic rewards such as pay.

The number of experiments on the effects of extrinsic rewards on intrinsic compensation is substantial; however, strong evidence to support or disconfirm the main principle of CET is mixed. Two metaanalytic reviews did not clarify this issue. For example, Eisenberger and Cameron (1996) examined dozens of studies that compared a rewarded group (verbal or tangible rewards) with a no-reward control group on two traditional measures of intrinsic interest: amount of free-time devoted to a task when the tangible or verbal reward is subsequently withdrawn or self-reported attitude toward the task (e.g., interest, enjoyment, or satisfaction). The results revealed no significant effect of reward condition and free-time, but did show that the relationship between reward condition and task-related attitudes was actually positive, which is inconsistent with CET. Deci et al. (1999) disagreed with the Eisenberger and Cameron (1996) conclusion and addressed them with a metaanalysis on the same issues. Still, they found no overall effect for performance-contingent rewards on the attitude measure of intrinsic interest (p. 644).

Fang and Gerhart (2012) conducted a field examination of CET to check whether Deci and Ryan (1985) may have focused too much on the potentially controlling aspects of rewards and not enough on the informational aspect. Consistent with this hypothesis, Fang and Gerhart (2012) found that employees covered by pay-for-performance plans reported higher intrinsic interest than employees not covered by pay-for-performance plans. Their finding is consistent with the fact that people often report pay as a motivator when it is perceived as recognition for good performance (Lawler, 1971).

As noted previously in this article, equity theory, and goal setting theory help explain the motivational impact of pay-for-performance practices. Expectancy theory also adds to the discussion. According to expectancy theory, an individual will choose to behave in a particular manner because they are motivated to select a specific behavior rather other behavior. The choice is primarily based on the desirability or valence of the outcome of the chosen behavior. Contrary to the premise of CET, a metaanalysis conducted by Locke et al. (1980) concluded: "Money is the crucial incentive … no other incentive or motivational technique comes even close to money with respect to its instrumental value" (p. 379). Subsequent research has continued to support their conclusion.

Ultimately, the body of evidence and thinking about the influence of tangible rewards (pay) on motivation and subsequent job performance is mixed. Reasonably, there is some merit to both perspectives on theoretical rationale and evidence. Perhaps the issue is not whether pay undermines motivation, but, rather, the conditions that influence that relationship. Undoubtedly, continued research will help shed further light on this important matter.

Job Performance

According to Motowidlo (2003), *job performance* is defined as the total expected value to the organization of the discrete behavioral episodes that an individual carries out over a specified time period. Those researchers emphasize two key issues in this definition. First, performance is an aggregated property of multiple, discrete behaviors that occur over time. Second, the property of behavior to which performance refers is its expected value to the organization.

Two performance criteria – mean performance and performance variation – are among the most commonly studied indicators in pay-for-performance research. According to Reb and Cropanzano (2007), average performance evens out employee's contribution to an organization. Average performance evens out variations from the mean that might be due to passing influences outside the control of the employee.

Following this rationale, past research found that average performance strongly predicts variance in pay and reward allocation (Barnes and Morgeson, 2007; Zhou and Martocchio, 2001), largely because typical, or average, performance represents the dominant conceptualization of performance (Rushton et al., 1981). In the pay-for-performance context, it is eminently reasonable to expect that higher mean performance will lead to positive changes in compensation level.

Performance variation also plays a role in compensation award decisions. Sturman (2007) maintains that long-term or directional changes over time are differentiated from short-term fluctuations, or unsystematic variation of performance. Within-person performance variation can be due to a variety of factors, including affective state (Weiss and Cropanzano, 1996). Between persons, some individuals may show large variation in performance, that is, are inconsistent, whereas others show little variation, that is, perform consistently around the mean level or a long-term trend.

According to Barnes et al. (2012), there are several reasons to expect that performance variation of greater magnitude is associated with smaller compensation. By definition, it is easier to predict the performance of employees who show little performance variability as compared to those who show high variability. Organizations tend to value predictability. Employees performing inconsistently can create uncertainty and disruptions for team members and other parties dependent on the employee, sometimes making it difficult to plan and perform interactively. This increases the risk of performance failures, coordination problems, and disrupted activities for other employees who are downstream in interdependencies.

Moreover, inconsistent performance has been found to lead to attributions of negative traits (Fox et al., 1995) such as undependable. The word undependable, which is one of the

hallmarks of the personality trait conscientiousness (Barrick and Mount, 1991), could be linked to high variability. Empirically, at least one study has found high performance variability to be associated with lower pay (Barnes and Morgeson, 2007). Organizations may pay higher compensation to more consistent performers in an effort to reward and retain these valued employees.

Executive Compensation

From an economic standpoint, the chief executive officer (CEO) is the seller of his or her services, and the compensation committee is the buyer of these services. Under classic economic theory, a reasonable price is obtained through negotiations that are at arm's length between an informed seller and an informed buyer. An awkward situation can result when the CEO hires a professional compensation director or compensation consultant. In this case, the compensation consultant who makes the recommendation to the compensation committee works for the CEO. In theory, the CEO hires the consultant to perform an objective analysis of the organization's executive pay package and to make whatever recommendations the consultant feels are appropriate. This relationship has the potential to promote a conflict of interest because of the perceived pressure for the consultant to protect the CEO's financial interests. The irony is that the consultant is often viewed as representing the shareholders' interests. In a sense, the buyers of the CEO's services are the shareholders and their representatives, the compensation committee of the board of directors. They tend to act upon the compensation consultant's recommendation (Walters et al., 1995).

Different individuals and groups participate in setting executive compensation. They include compensation consultants, compensation committees, and boards of directors. Each plays a different role in setting executive compensation.

Executive compensation consultants usually propose several recommendations for alternate pay packages.

Consultants make recommendations about what and how much to include in executive compensation packages based on strategic analyses, which entail an examination of an organization's external market context and internal factors. Examples of external market factors include industry profile, information about competitors, and long-term growth prospects. Financial condition is the most pertinent internal factor regarding executive compensation. Strategic analyses permit compensation consultants to see where their client organization stands in the market based on external and internal factors. Strong organizations should be able to devote more financial resources to fund lucrative executive compensation programs than weaker organizations. According to Crystal (1991), more often than not, executive compensation consultants find themselves in conflict-of-interest situations: "Ostensibly, compensation consultants were hired by the CEO to perform an objective analysis of the organization's executive pay package and to make whatever recommendations the consultant felt were appropriate. In reality, if those recommendations did not cause the CEO to earn more money than he was earning before the compensation consultant appeared on the scene, the latter was rapidly shown the door" (p. 12).

Executive compensation consultants' professional survival may depend on recommending lucrative compensation packages. Recommending the most lucrative compensation packages will quickly promote a favorable impression of the consultant among CEOs, leading to future consulting engagements.

Since 2008, the US Securities and Exchange Commission rulings require organizations to include the identity of the consulting firm in public disclosure statements. This ruling has created concerns about possible conflicts of interest for consulting firms that also provide consulting services in other areas (e.g., performance management and change management) for the same client firms. Executive compensation consulting represents just one of many possible areas of management consulting. The conflict potentially arises when a consultant intentionally recommends a more-lucrative-than-warranted executive compensation package in the hope of gaining management favor and additional other management consulting opportunities. Of course, compensation consulting firms are concerned about the public image of possible conflicts of interest and have considered a variety of tactics to ensure the integrity of their recommendations to client firms. For example, there has been some speculation that executive consulting practices will be spun off into independent businesses. Many organizations are concerned about their own public image and have instituted policies to prevent compensation consultants from conducting other work for management.

The board of directors represents shareholders' interests by weighing the pros and cons of top executives' decisions. Boards of directors have approximately 15 members. These members include CEOs and top executives of other successful organizations, distinguished community leaders, well-regarded professionals (e.g., physicians and attorneys), and possibly a few top-level executives of the organization.

Boards of directors give final approval of the compensation committee's recommendation. Some critics of executive compensation have argued that CEOs use compensation to coopt board independence. CEOs often nominate candidates for board membership, and their nominations usually lead to candidates' placement on the board. Board members receive compensation for their service to the boards. It is not uncommon for a board member to earn more than $50 000 per year plus a fee ($10 000 or more) for each board meeting attended. Along with monetary and stock compensation, organizations are using such benefits as medical insurance, life insurance, and retirement programs to attract top-notch individuals to join boards of directors. In general, board members' failure to cooperate with CEOs may lead either to fewer benefits or their removal. "The board determines the pay of the CEO. But who determines the pay of the outside directors? Here, a sort of formal Japanese Kabuki has developed. The board of directors determines the pay of the CEO, and for all practical purposes, the CEO determines the pay of the board of directors. Is it any accident, then, that there is a statistical relationship between how highly the CEO is paid and how highly his outside directors are paid?" (Crystal, 1991: pp. 20–21).

Board of directors members within and outside the organization make up an organization's compensation committee. Outside board members serve on compensation committees to

minimize conflict of interest. Thus, outside directors usually are the committee's membership majority.

Compensation committees perform three duties. First, compensation committees review consultants' alternate recommendations for compensation packages. Second, compensation committee members discuss the assets and liabilities of the recommendations. The complex tax laws require compensation committees to consult compensation experts, legal counsel, and tax advisors. Third, based on these deliberations, the committee recommends the consultant's best proposal to the board of directors for its consideration.

Although pay-for-performance is the public rationale for setting executive compensation, reality is often quite different. Three alternative theories explain the principles and processes for setting executive compensation: agency theory, tournament theory, and social comparison theory.

Agency Theory

Ownership is distributed among many thousands of shareholders in large organizations such as Microsoft, General Electric, and the International Business Machines Corporation (IBM). For example, owning at least one share of stock in IBM bestows ownership rights in IBM. Each shareholder's ownership is quite small, with most owning far less than 1% of the total shares. Inability to communicate frequently or face to face to address business concerns is a major disadvantage of thousands of shareholders.

According to *agency theory*, shareholders delegate control to top executives to represent their ownership interests; however, top executives usually do not own majority shares of their organizations' stocks. As a result, executives usually do not share the same interests as the collective shareholders. These features make it possible for executives to pursue activities that benefit themselves rather than the shareholders. The actions of executives on behalf of their own self-interest are known as the agency problem (Jensen and Meckling, 1976). Executives may specifically emphasize the attainment of short-term gains (e.g., increasing market share through lower costs) at the expense of long-term objectives (e.g., product differentiation). Boards of directors may be willing to provide executives generous annual bonuses for attaining short-term gains.

Shareholders negotiate executive employment contracts with executives to minimize loss of control. Executive employment contracts define terms of employment pertaining to performance standards and compensation, specifically current and deferred compensation and benefits. The main shareholder objective is to protect the organization's competitive interests. Shareholders use compensation to align executives' interests with shareholders' interests. As discussed earlier, boards of directors award organization stock to align executives' interests with shareholders' interests.

Tournament Theory

Tournament theory casts lucrative executive compensation as the prize in a series of tournaments or contests among middle- and top-level managers who aspire to become CEOs (Lazear and Rosen, 1981). Winners of the tournament at one level enter the next tournament level. In other words, an employee's promotion to a higher rank signifies a win, and more lucrative compensation (e.g., higher base pay, incentives, enhanced benefits, and perks) represents the prize. The ultimate prize is promotion to CEO and a lucrative executive compensation package. The chance of winning competitions decreases dramatically as employees rise through the ranks: There are fewer positions at higher levels in corporate hierarchical structures.

Social Comparison Theory

According to *social comparison theory*, individuals need to evaluate their accomplishments, and they do so by comparing themselves to similar individuals (Festinger, 1954). Demographic characteristics (e.g., age or race) and occupation are common comparative bases. Individuals tend to select social comparisons who are slightly better than themselves (Festinger, 1954). Researchers have applied social comparison theory to explain the processes for setting executive compensation (O'Reilly et al., 1988).

As we discussed earlier, compensation committees play an important role in setting executive compensation, and compensation committees often include CEOs from other organizations of equal or greater stature. Based on social comparison theory, compensation committee members probably rely on their own compensation packages and the compensation packages of CEOs in organizations of equal or greater stature to determine executive compensation.

National Culture as Context

Cultural values are probably a key factor in the effectiveness of pay-for-performance systems, or, for that matter, whether pay-for-performance is even compatible in particular cultural contexts. Culture is defined as "the human-made part of the environment (Herskovits, 1955). It has both objective elements- tools, roads, appliances- and subjective elements- categories, associations, beliefs, attitudes, norms, roles, and values" (Triandis, 1994: p. 113). Cultural values shape work-related attitudes and behaviors (Triandis, 1994). Culture also influences the domain of normative behavior (e.g., behavior that is desirable versus condemned for members of the culture), defines roles for individuals in the social structure, and prescribes guiding principles and values in one's life. As a result, culture specifies how things in the environment, including an organization's practices, policies, and procedures, are to be evaluated and subsequent reactions to such procedures (Robert et al., 2000).

These cultural values are apparent in compensation systems. The predominant bases for pay in the United States are performance and knowledge, which represents equity (Heneman and Werner, 2005). According to these cross-national studies, there are three primary rules governing individuals' compensation award decisions: equity, equality, and need. The equity rule specifies that individuals should be rewarded on the basis of their contributions such as task performance. The equality rule specifies that individuals should be rewarded equally, regardless of their contributions to the group or the organization. And the need rule states that

individuals should be rewarded on the basis of their personal needs. In general, previous studies, which mostly use undergraduate student samples, have found that individuals in collectivism-dominated nations tended to prefer the equality rule or the need rule, because individuals who hold the collectivist cultural values are concerned with interpersonal relationships. In contrast, individuals in individualism-dominated nations tended to prefer the equity rule, because they are less concerned with relationships and more concerned with task contributions (Bond et al., 1982; Hui et al., 1995; Kim et al., 1990). However, there is at least one notable exception to these findings. Specifically, using a sample of actual employees, Chen (1995) concluded that individuals in China – a collectivism-dominated nation – chose the equity rule, yet individuals in the US – an individualism-dominated nation – chose the equality rule.

For example, just one (among many) noteworthy cultural contrast exists between the US and the People's Republic of China (PRC). The differences between the US market economy and the PRC's centralized government-controlled economy sets the stage for cultural clashes. For decades, the Chinese government owned and operated virtually all business organizations. The Communist party places substantial emphasis on equal contributions to society, group welfare, and the concern for interpersonal relationships. In addition, the Communist party calls for greater emotional dependence of Chinese citizens on their employers. Further, it expects employers to assume a broad responsibility for their members. Zhou and Martocchio (2001) demonstrated support for the difference in ideals when Chinese (employed in the People's Republic of China) and US managers made decisions about monetary and nonmonetary compensation awards.

These ideals are evident in the Chinese workplace and in compensation practices. Employers provide housing and modest wages for food and clothing. The Chinese receive health care under government-sponsored protection programs. Because of the Communist ethic, the Chinese do not identify very well with pay-for-performance programs though that is slowly changing as a capitalist presence creates for-profit organizations.

Peace

Johan Galtung, TRANSCEND Peace University

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Peace is seen as a transnational, transdisciplinary, and translevel – from inner peace to civilizations – concept. There are two aspects: negative peace as absence of violence, and positive peace as cooperation and harmony. A formula is presented based on equity and harmony for positive peace, and reconciliation of traumas and resolution of conflicts to avoid violence for negative peace.

Summary and Overview

The point of departure for peace is the broad, basic suffering fulfillment distinction, for all life. The double task of peace is to reduce the suffering by violence – negative peace – and increase the fulfillment – positive peace. The two can be pursued together.

One basic diagnosis for violence is underlying, *unresolved conflicts at present*, simple, complex, or structural (see Johan Galtung, *A Theory of Conflict*, TRANSCEND University Press, 2010; Parts Two, Three, and Four respectively). The parties are coupled; the task is to change this coupling from incompatibility to compatibility of goals, or to no coupling at all.

Another basic diagnosis for violence is *unconciliated traumas from the past*, inflicted by the parties in the coupling, or by some other party. The task is to clear the past, closure, and create a future together. But reconciliation should not serve as a pretext to neglect the conflict resolution job lest it becomes pacification.

In addition, there is the equity job to take care of, for not only mutual, but not too unequal fulfillment, harmony, and emotional resonance. But these two positive peace tasks may come to nothing if traumas and conflicts are not adequately handled.

Peace politics is the transformation from direct and structural violence to negative and positive peace by peaceful means. Nonviolent struggle, mediation, and reconciliation can be substituted for war, guerilla-terrorism, and negotiation to win. The goals are negative and positive peace, working on both together, not one after the other.

That opens for four stages beyond negative peace: symbiosis, transcendence, synthesis, and absorption. How far we want to go depends on the concrete case, but as a minimum there should be some *project*, some *peace construction*, with *cooperation* for mutual and equal benefit and *harmony*, attitudinal resonance. Transcendence and synthesis may come when old identities are waning and the capacity to handle equity and new conflicts is waxing. Peace is a never-ending process.

What Is Peace? An Operational Definition

Peace cuts across history, geography, and levels of human organization; from inner and interpersonal peace via states and nations to regional and civilizational relations. Definitions should reflect positive peace as cooperation and harmony, and negative peace as absence of violence; the latter not only as absence of direct, intended violence, acts of commission, but also of indirect structural violence by acts of omission, and by cultural violence, justifying one or the other. Peace is incompatible with massive, lethal, and social inequality – like health is incompatible with tumors and circulation problems with no overt pain or fever. Both are ideals, sums of all good things.

Definitions should serve thought, speech, and indicate action. This formula defines peace operationally, in terms of four tasks (the formula logic is structural peace – equitable cooperation – and cultural peace – empathic harmony knowing and feeling the reality of other – threatened by direct violence from unreconciled trauma and unsolved conflicts. For more details, see Johan Galtung, *A Theory of Peace*, TRANSCEND University Press, 2013, Part One. For more about the formula, see Johan Galtung and Dietrich Fischer, *Peace Mathematics*, TRANSCEND University Press, 2012, pp. 28–32.):

$$\text{Peace} = \frac{\text{Equity} \times \text{Harmony}}{\text{Trauma} \times \text{Conflict}}$$

The formula applies across time, space, level, from peace with nature, and inner peace to, for some, peace with their God. Needless to say, no academic discipline, or civilization, has any monopoly on 'peace.'

There are two factors in the numerator: *the more the better*; and two in the denominator leading to violence, *the less the better*. The definition relates to the reality of peace, not to literature about peace and is operational, neither semantic, nor 'essentialist.'

The four factors or tasks can be spelt out:

1. *More equity*: cooperative behavior for mutual and equal benefit
2. *More harmony*: empathic attitudes of emotional resonance, in the daoist sense of enjoying the joy, and suffer the suffering, of other
3. *Less trauma*: reconciliation, clearing the past, acknowledging wrongs, wishing them undone, and dialogs to create a future together
4. *Less conflict*: resolution, acceptable and sustainable, making incompatible goals compatible, and changing negative attitudes and behavior

Using marriage as an example, parity and empathy are basic, but unreconciled traumas from the past and unresolved conflicts may cause verbal or physical violence and cannot be left unattended.

Political examples of the four tasks carried out successfully:

Equity: the 1950–58–92 French–German, then as European Economic Community (EEC), then as European Union (EU), European cooperation on reasonably equal terms; now (2013) threatened by the economic inequality between Germany and the EU periphery;

Harmony: the feminist revolution has made many men understand how the man–woman divide or fault line looks from a woman's point of view; women being familiar with the prejudices associated with patriarchy.

Reconciliation: the South African Truth and Reconciliation Commission exchanging confession of political crimes (and contrition and compensation, if possible) for amnesty.

Resolution: black–white relations in the United States, moving toward racial equality of opportunity.

How good EU is at the other three is now being tested; the same applies to the feminist revolution, race in South Africa and the United States. Peace as defined operationally by the formula is a demanding agenda.

Major insights in *how to* are provided by worldviews, religion, and philosophy, but they are not unproblematic. Thus, reconciliation in South Africa built on the Zulu *ubuntu*, "I exist because you exist, we are in each other," defining a strong spiritual coupling in a *we-culture*. The unit of suffering and joy is a we, not two separate, parallel I's; problematic to an individualistic West that may prefer negative peace to being coupled together in positive peace.

Compare this to the *Golden Rule*, positive (or negative):

Do (do not) unto others what you (do not) like them to do unto you. The subject for violence avoidance and peace is an individual "you"; the ethical budget is egocentric I-culture, not collective we-culture. In addition, be careful: "their tastes may be different" (GB Shaw).

The same applies to the *Kantian categorical imperative*: "Act so that the principle of your intention always could serve as the basis for world law" (be generalizable, universalizable). This is a traffic rule for coexistence: Kant wanted a multilateral normative umbrella, not only *Golden Rule* bilateralism. Both are useful rules for positive coexistence in an I-culture, but do not produce the resonance of a we-culture. Or Mo Tzu's universal love as opposed to partiality, (Mo Tzu (one of the 'hundred philosophers' 551–233 BC) argues universal love, also of one's enemies, as opposed to the partial love only of one's friends. The rulers must start: "Now universal love and mutual benefit are both profitable and easy beyond all measure. The only trouble, as I see it is that no ruler takes any delight in them. If the rulers really delighted in them, promoted them with rewards and praise, and prevented neglect of them with punishments, then I believe that people would turn to universal love and mutual benefit as naturally as fire turns upward or water turns downward, and nothing in the world could stop them." *Mo Tzu*, *Basic Writings*, New York, London: Columbia University Press, 1963, p. 49.) long before the universalism of Christianity, Kant, or human rights.

Being well together by fulfilling each other is *positive peace*; with mutual assured bliss (MAB), as the extreme – an abstraction found in religious discourses but also in love defined as the union of the unions of body, mind, and spirit. Inflicting suffering on each other is typical of *direct violence and war*, with the mutual assured destruction (MAD) of the Cold War nuclear arms race, as the extreme; not an abstraction. One doing well and the other doing badly is typical of *structural violence*. Neither fulfilling each other, nor inflicting suffering, is typical of *negative peace*: there is passive peaceful coexistence, neither violence, nor positive peace; mutual irrelevance.

Peace politics can be seen as intended efforts to reduce direct and structural violence for negative peace – not accepting exploitation of one by the other as 'peace' even if there is no verbal or physical violence – moving on to positive peace with ever more cooperation for mutual and equal benefit, and more empathy for harmony; feeling each other's suffering and fulfillment as parts of one's own. Two traps on the way: ignoring exploitation and repression as justified by cultural violence – economic and cultural powers are seen as 'soft power' – and being satisfied with the negative peace of mutual irrelevance. (Mutual isolation is problematic in a globalizing world with the means of transportation–communication reaching every corner of the world; sometimes as means of structural violence like means of destruction are the means of direct violence; as important in human history as Marx' means of production.) If past traumas and present conflicts are not mediated, negative peace will be lost, and unless the coupling is not equitable and harmonious, there will be no positive peace, and sooner or later acts of violence.

Peace and Related Concepts

Security stands for the absence of direct violence, the threat thereof, and absence of efforts to change the 'normal' interaction and division of labor between persons and between states. Security stands for *stability*, *status quo*, law and order; generally favored by those who benefit from that concept. Positive peace with equity is too revolutionary, standing both for equality and a togetherness close to fusion, like in a good marriage or community. Absence of positive peace opens for freedom, for exploitation, and for freedom to exploit.

The Japanese concept of *kyosei* (see Yoichiro Murakami and Thomas J. Schoenbaum (eds.) *A Grand Design for Peace and Reconciliation: Achieving Kyosei in East Asia*. Cheltenham, UK, and North Hampton, Massachusetts, USA: Edward Elgar, 2008), conviviality, comes closer to positive peace with less emphasis on equity; mutual fulfillment, but not necessarily equally much fulfillment. There is much of that in the classical Japanese company; less in concrete Japanese foreign policy, without reconciliation, resolution, and equity.

Article 9 in the constitution, depriving Japan of the right to offensive war, is compatible with no joint projects like an East Asian Community, no harmony, no reconciliation with the victims of Japanese imperialism. The preamble mentions trade, but Japanese trade is not known for equity. The peace concept underlying *A9* was only negative.

Human security is more problematic. 'Human' has positive connotations, but 'security' has the negative connotations mentioned, including military intervention. 'National security' also conveys an image of a hedgehog turning inward with noninviting quills outward, attending to the inside at the neglect of the excluded outside. But inside seven types of human security may be met: food, health, environment, personal, economic, community, and political security. (See, for instance, the *Philippine Human Development Report 2005*,

p. 5.) However, there is no *kyo*, con, sym, cocreation with others; it comes from the inside and from above. That is where 'mutuality and equality' enters the peace concept, like in the *mutual and equal benefit* of the *Panchshila* of Zhou Enlai and Nehru, for China–India, in 1954.

The military, extending a violent arm to violent arms: depends on how far the arms reach. If only within the country, the arms are defensive of Self; if also outside they are offensive, violent to Other. Even if not used the threat of use is direct psychological violence to the mind of Other as fear; and to the spirit of both by impeding positive peace. Defensive defense neither offends, nor provokes; is neither violence, nor positive peace, but the negative peace of mutual security.

Justice is ambiguous, divided into *criminal* and *social* justice, the former into *punitive* and *restorative*, and the latter into *distributive* and *equitative* justice. Depends on what is meant.

Under *punitive justice* an actor is arraigned into court for adjudication. If found guilty, punishment, meaning violence, follows.

Under *restorative justice* an actor who has broken a law will be attempted restored to society, for instance through community work. This concept could be extended to guilty states, doing 'world work.'

Under *distributive justice* the focus is on 'equality' as equal opportunity; no correlation with gender, race, etc.; low dispersion of wealth; lifting the social bottom up. All contribute to equality.

Under *equitative justice* the focus is on patterns of interaction (like parity in marriage) that generate mutual and equal benefit.

Punitive justice as victor's justice are continuations of war by legal means; no healing traumas, solving conflicts, and building projects.

Restorative justice may help reconciliation, solve conflicts, and open for projects, like inviting Germany into the European Community.

Distributive justice will promote equality, which facilitates dialogue between equals, empathy, nonviolence, equity, and harmony.

Equitative justice: builds peace directly into the structure.

Punitive justice may prolong violent struggle to deny the other side victor's justice, and be counterproductive when used against nonviolent struggle. The other three may be peace-productive.

Rule of law is also ambiguous, like the Ten Commandments strong on forbidding acts of commission, but permissive of acts of omission, all those doing nothing. This opens for huge structural violence justified by cultures weak on prescribing the good acts of commission. Thus, "Thou shalt not lie" changes character when adding "but share generously your truths with others" (as opposed to patents). For world rule through world law a more positive, less punitive, rule of law is needed; with rewards, not only punishment. Moreover, social ills like slavery and colonialism were not so much outlawed as being overtaken by other structures, some of them liberating, others not.

Human rights are better, but to the individualist focus peoples' rights have to be added, like the right of villages to survive as human habitats, of traditional crafts to survive, and of clans and tribes to be recognized as juridical persons. The right of (some) nations to (some) self-determination is not enough. A better balance between individual and collective rights is needed for human rights to serve, as they 1 day probably will, as a world constitution.

Democracy matters, but to the individualist one-person one-vote focus and majority rule – after debate to win that majority – dialog to consensus, more satisfactory to we-cultures, should be added. For world democracy add a democratic UN without big power veto, and an elected UN Peoples' Assembly with the member states as constituencies.

Ho'o pono pono is an ingenious Polynesian reconciliation and resolution method, focusing less on perpetrator and victim and more on the community as the basic victim, unable to prevent violence because of too many doing nothing. These acts of omission are identified by the process, and then turned into positive acts of commission.

Thus, there are many peace-related concepts. The purpose of such exercises is to identify what there is of peace in a concept, and to identify what is missing; in a never-ending concept dialog.

Negative Peace: The Absence of Violence

A year with one war between states is often seen as a war-year, not counting all the peaceful relations, the days not at war, and the people on both sides not participating. We have become so mesmerized by war and blind to the prevalence of peace as absence of violence – even if only because of mutual irrelevance and distance – as the general rule for humans that we do not even see it. But such errors keep the lie about innate violence by 'human nature' alive, giving humans a bad name, and a worse reputation than humans deserve. (The UNESCO *Sevilla Declaration* is one way of doing this, declaring that there is no scientific basis for the idea that violence-war is innate. Missing in the declaration is the idea that there are positive ways of handling trauma and conflict, may be not innate either, but like war easily learnt.)

Unresolved conflict has been identified as a key cause of violence, and solution as the remedy. Violence is to hurt and harm to the point of incapacitating Other(s); conflict is incompatibility in the means-ends complexes pursued and used by the parties. From "Other pursues his goals with his means and impedes me from doing the same" does not follow that "Other stands in my way," but that "Other's goals stand in the way of my goals." A puzzle in search of a solution, and there seem to be five approaches, starting with the violent ones.

No. 1, *modern war*, to win and dictate the solution, is now waning between states: destructive power is too high and invulnerability too low; hence the use of state terrorism, unleashing destruction on soft targets far away, often unable to hit back.

No. 2, *guerilla, terrorism*, to win and dictate the solution, less lethal than state terrorism, takes more time; but the asymmetry seems to favor guerrilla as judged by Viêt Nam (The classical exchange when levels 1 and 2 Vietnam war turned into level 3, negotiation between United States and Viêt Nam: "You were never able to beat us in open battle!", "Correct. But it is immaterial." It is worth remembering that at level 2 there is no beginning and no end, nor formal declaration of war nor capitulation. That plays in their favor, exhausting Other's resilience.), Afghanistan, Iraq, etc. It is the continuation of war by informal means.

No. 3, *negotiation*, is the continuation of war by verbal means, *debate*, ideally so that the strongest arguments based on data, values, and theory win. There is polarization between two sides of the table, and winners and losers, like in Nos. 1 and 2.

No. 4, *negative nonviolence*, like the multiseason Arab spring, is the continuation of war by such nonviolent means as noncooperation and civil disobedience, with winners and losers. As revolt effective, as revolution, changing the system, too shallow, and too negative.

No. 5, *positive nonviolence*, conversion, not coercion, bridging polarization (Polarization in "us vs them" glorifies us and demonizes, dehumanizes them to objects not protected by human empathy with each other. Depolarization is an important part of the work for negative peace, and cooperation on conflict solving is already a first step for positive peace. The Tajfel–Turner and Tropp–Pettigrew traditions in social psychology have much to say about social identity and intergroup relations, but less on identifying and mediating conflict and trauma.) in *dialogue* searching together for solutions, without or with mediator, *mapping* the conflict – who are the parties, what are their goals and means – *testing* the goals for legitimacy – legal? human rights? basic needs? – and *bridging* between legitimate goals, jointly searching for a new reality. It calls for peace education in schools, peace journalism in the media, peace in the arts; like No. 1 calls for training to kill, militarized universities, No. 2 for camps, etc.

No. 4 for struggle and No. 5 for solutions are normal human ways; the others are aberrations, and should be known as such. (The rest is a question of knowledge and skills. This author's contributions are in the two books *Transcend & Transform*, 2003, and *50 Years: 100 Peace & Conflict Perspectives*, 2008.)

Unconciliated trauma; wounds from a conflict, even forgotten, have also been identified as cause of violence. Five approaches (And the book corresponding to the preceding paragraph is Joanna Santa Barbara, Johan Galtung, Diane Perlman, *Reconciliation*, TRANSCEND University Press, 2012.):

No. 1, *revenge* according to the classical rule of *lex talionis*, an eye for an eye, etc., carried out by the victim, or by the state.

No. 2, *displaced aggression*, violence in any direction, also against self. Violence leads to new trauma leads to violence leads to trauma *ad inf.*, like family feuds, *vendetta*; no end, no closure.

No. 3, *negotiation*, extracting compensation from the perpetrator also in monetary terms. Superficial, but may lead to shallow closure.

No. 4, *visibility*, "see what you have done to me"; museums, parks, monuments for traumas already suffered, may lead to shallow closure.

No. 5, *conciliation*, opens for the whole complexity, conscious and subconscious. If the perpetrator is traumatized by traumatizing the victim, they may have a joint interest in clearing the past by wishing it undone, working for an acceptable future, and for closure.

No. 5 one way or another is the normal human way; the other four are aberrations, and should be known as such (see Joanna Santa Barbara, Johan Galtung and Diane Perlman, *Reconciliation: Clearing the Past, Opening the Future*, TRANSCEND University Press, 2012).

Positive Peace: The Presence of Cooperation and Harmony

Level I: *Symbiosis = Equity + Harmony*. There is cooperation for mutual and equal benefit, and there is emotional resonance. Another term would be active peaceful coexistence, as opposed to the passive peaceful coexistence of negative peace.

Level II: *Transcendence: A new actor is born*. The parties are still there, but something new has emerged. In the integration language for states they start "talking with one voice," "having a joint foreign and security policy," etc. The term often used for level I is community, confederation (German: *Staatenbund*); and for level II the terms are union, federation (German: *Bundesstaat*).

Transcendence means something above, beyond; among states, multistate conferences, a permanent secretariat, a commission that becomes more than the sum of the actors. The process can be seen as follows:

1. Negative peace: separate goals, separate means; avoiding violence.
2. Positive peace I: separate goals, shared means-resources.
3. Positive Peace II: shared goals, shared means-resources.

In cohabitation the parties share their resources, but preserve the autonomy of having separate goals. In a marriage they share a goal, building a happy marriage, beyond the sum of the two parties.

That brings us to the next level:

Level III: *Synthesis*. Feudal counties, duchies, etc. die; a state is born. States gradually die, regions are born. Regions gradually die, a world is born. We are right now living the drama of all these processes in different parts of the world.

The resources, the means, have already been pooled; the goals have been aligned. They are not only compatible, but identical. Out of numerous I-ness's a new we-ness, of a new kind, has emerged. The old actors, like old people, have had their days, but the new actors are not like a younger generation merely replicating the old; but a transition to a new era in human history.

Level IV: *Fusion, absorption*, found in the religious discourses, but often reserved for the beyond, the afterlife, for souls only. The ultimate absorption-union is with God in Christianity and Islam, with each other in the Hindu nirvana concept, with the network of all life in Buddhism. But the human individual spirit is capable of level IV without dying, as absorbed, fully devoted, in the nation, in the civilization, in humanity; in a marriage with a fusion of partners.

There is ambiguity in positive peace. At levels I and II between states, for instance, war has become 'unthinkable' if the integration manages to handle, constructively, complex conflicts with high numbers of parties and goals. But that is a huge order. If unable to handle conflicts, the coupling may break up, parties may decouple, hopefully only down to level 0, negative peace, not further down to violence.

The real crisis may come at level III, let alone level IV. As the process proceeds, the identity of the actors is eroding. Thus, for the United Kingdom, France, and Germany to be absorbed into Europe, with no identity of their own, will be hard, let alone the United States under UN.

The solution lies in seeing the levels less as linear progress, more as parallel processes. A couple will delight in the union of

unions of body, mind, and spirit as bliss, but find it exhausting and proceed with one at the time. A political union may be needed in crisis, but revert to level I under more normal conditions.

The levels are modes of coexistence, not life sentences.

Negative peace as mutual assured survival (I am indebted to Diane Perlman for this felicitous term, a common sense between MAB and MAD) is attractive in its simplicity, but positive peace has much more to offer. Active peaceful coexistence imposes mutual rights and obligations on us, the trick to make the relation peaceful lies in the equity and harmony. The parties will be well advised to train in both and not go for higher levels of positive peace than they can master. And Western individualism and state sovereignty may impede positive peace.

Massive Category Killing as the Extreme Peace Negation

Concepts are better understood contrasted with their negations. The Black Plague stimulated health studies, and twentieth-century genocides stimulated peace studies; not only *Shoa*, but also MAD, by the logic of the Cold War nuclear arms race. The nuclear arms race as structure was blamed, not an evil perpetrator against innocent victims. This discourse switch from evil party to bad relation-orientation was among the factors ending the Cold War.

1. *Definition*: Genocide = Massive Category Killing, MCK, meaning by.
2. Massive = All of a kind available, till exhaustion–saturation.
3. Category = The same ascribed or achieved characteristics.
4. Killing = Avoidable life deprivation, by commission or omission.

"There is no good German but a dead German" are words typical of wars. The target is 'all of a kind,' defined by ascribed or achieved attributes; with massive air raids, year after year. Or massive ethnic cleansing, year after year. By the MCK definition both are genocides. Lemkin's (Raphael Lemkin, 1900–59, Polish lawyer) focus on *genus*, people, opens for that. But the massive killing of Germans was done by World War II (WWII) winners, of Jews by WWII losers; ethnic cleansing of Moors and Jews in Spain from 1492 was by victors, Serbian acts in Yugoslavia by losers. Losers commit genocide, winners not; 'massive category killing' covers both.

The 'category' is a set of humans, violence – like peace – is a relation, the bridging concept is the *fault line* between categories:

1. *Definition*: Fault line = division between categories of humans.

Across fault lines massive structural violence may grow, exploiting, repressing, alienating; with sparks of massive direct violence. The genocide concept focuses on the effect, less on the fault line cause.

The atrocious effect comprises all three types of violence:

1. Direct violence = Intended, by *actors* hurting–harming–killing.
2. Structural violence = Unintended, by *structures* hurting–harming (exploitation, repression, and alienation).
3. Cultural violence = by *cultures* legitimizing either violence.

The cultural violence justifies the direct and structural violence that causes each other.

There are at least eight fault line causes with such effects: humans/nature, men/women, middle-aged/young/old, white/colored, 'normal'/deviants, high/low class (with four types of class: economic, military, political, cultural; generally powerful vs powerless); dominant/dominated nations; center/periphery states.

If we combine the fault lines with the two forms of violence, direct actor violence and indirect structural violence (cultural violence is not itself violence, but very important as it legitimizes the other two), we get:

A basic paradigm for massive category killing

Private no.	*Fault lines*	*A: actor violence*	*S: structural violence*
1	Nature	Slaughter of 'beasts, savages, wilderness'	Depletion pollution
2	Gender	Killing women: abortion, infanticide, witch-burning	Patriarchy as prison of women, putting them 'in their place'
3	Generation	Privileging middle-aged	Schools as ghetto Homes as ghetto
4	Race	Controlling dangerous races	Eradication slavery Colonialism slavery
5	Deviance ● Criminal ● Mental ● Somatic	Controlling dangerous persons	 Euthanasia exclusion Euthanasia exclusion Euthanasia exclusion
6	Class ● Military ● Economic ● Political ● Cultural	Controlling dangerous classes Elimination	 Exploitation of body Repression of mind Alienation of spirit
7	Nation Culture Ideology	Genocide narrowly defined	State as prison of nations ruled by 'majority'
8	State Country Territory	War (killing for food, sacrifice, conquest)	Imperialism Isolating 'Pariah' states

Here are 16 types of MCK by pure logic, not by ideology. To focus on 7A only is selective, ideological.

The extreme peace negation, the total Table 7A, is atrocious; but 6-7-8S, massive structural killing of the poorest in periphery countries, is worse in numbers. And 2A, killing unborn and newborn girls, has by far outdone 7A. The focus in the table is moving over time, but one factor remains: 1A and

1S against animals may serve as training in taking life, an argument for vegetarianism.

The dominating world elite is human, male, middle-aged, white, 'normal,' powerful, from dominant nations (like Anglo-American), from center states (like United Kingdom–United States).

Today that elite is challenged by all its fault line opposites, including Mother nature. But the discourse is still focused on 7A, with cases like Armenia, Nanjing, Gulag-KZ, *Shoa*, Hiroshima, Indonesia, Cambodia, Rwanda; making actors visible as perpetrators and victims, but structures invisible as any focus on their victims – women, colored, etc. – might lead to deeper scrutiny of that elite.

To restore law and order they bring perpetrators to punitive justice – tribunals – and the guilty are punished, even killed. But adjudication also serves to acquit the judges, the non-indicted, structures and cultures, and future generations. The focus is narrow.

Some waning discourses still legitimize omitting other victims:

Nature: because animals are seen as soulless, feeling no pain and no bereavement, having no families.

Gender: because women were seen as born inferior to bear children, as emotional not intellectual, as temptresses, as being of Satan.

Generation: because the old generation has to make way for the next, and the young generation has to wait and first be adequately trained.

Race: because primitives are seen in the same way as animals or women.

Deviance: because criminals have excluded themselves, the mentally ill are unfit, the somatically ill are a burden to themselves and society.

Class: because class sorts the fittest from the less fit.

Nation: because some nations are seen as up front in human history, others as lagging behind, having to wait to be adequately trained.

States: because states (except Japan) have the right to war, and wars identify the fittest states to rule the world from the less fit.

There is also cultural violence built into academic disciplines making some of the 16 invisible: international studies covers only 8A, are often structure blind, like international (actually interstate) Law; best at 6A and 8A, but only as security studies. Lemkin's 7A insistence was at the time a breakthrough, and resisted.

The micro- and mesolevel social sciences, psychology–sociology, have made basic contributions studying prejudice and discrimination as cultural and structural violence; but rarely touching the MCK drama.

This selective approach to violence leads to a selective approach to peace, focused on actor, not structural violence, with a decreasing priority in the order $8 > 7 > 6 > 5 > 4 > 3 > 2 > 1$.

Peace studies, spanning all levels of human organization and all types of violence and peace, must cover all 16 (and not only 7A and within 7A *Shoa* only, excluding the suffering of other peoples (Thus, *nakba*, the horrors suffered by the Palestinians at the hands of the Israelis, from 1948 up till today, was massive and directed against a category, but not MCK. What was killed was and is a society; not genocide, but *sociocide*.)).

And peace politics has to dampen all fault lines through equity and harmony to overcome discrimination and prejudice, reconciliation for past atrocities, and creative conflict resolution for the present.

This is what peace theories and practice are up against, like health theories and practice are up against *massive lethal diseases*, contagious from the outside as epidemics, even pandemics; structural from the inside as cancers, circulation diseases, and mental disorders with an 'epidemiological shift' from the former to the latter; for health, as for peace from direct to structural violence. States are waning in salience, nations not; interstate wars are less frequent (like killing of monarchs with monarchy waning or like wars of liberation from colonialism as classical colonialism no longer matters. Interstate wars show signs of decline because the states, except for the biggest, and with the states the state system, decline in salience as they get absorbed into regions. Steven Pinker, *The Better Angels of Our Nature: Why Violence Has Declined*, London: Penguin, 2011 adds important psychology to historiography, but his violence and peace concepts do not reflect contemporary reality.) but massive inequality is increasing, changing the focus in the peace formula to equity.

Peace and Nonviolence: Anthropological Aspects

Leslie E Sponsel, University of Hawaii, Honolulu, HI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The accumulating scientific evidence proves beyond any doubt that nonviolent and peaceful societies not only exist, but are actually the norm throughout human prehistory and history. This article demonstrates and elucidates this scientific fact through a historical inventory of the most important empirical documentation and a summary of the most seminal cases. Next it reveals the significance for anthropology of the provocative new perspective and possibilities of the conceptual framework of nonkilling and of the transformation toward that ideal. Finally, it briefly discusses the obstacles to further advancing this fertile and crucial research frontier while refuting the spurious assertions of opponents.

Introduction

Nonviolence and peace are natural, ubiquitous, and normal in the human species throughout its evolution and adaptation. In fact, for well over a million years evolution has selected for a human nature that is naturally inclined toward nonviolence, peace, cooperation, reciprocity, empathy, and compassion in the context of nomadic forager societies that comprise 99% of human existence. Otherwise the species would not have survived and flourished.

Serial and mass murder, and especially in the form of warfare justified by whatever rationalizations, are relatively recent aberrations in human cultural evolution and prehistory, and are uncommon in history as well. Normal refers to the statistical sense of nonviolence and peace as common. Normal also refers to the moral sense in that nonviolence is valued as an ideal, what is right. All of the major religions have core principles proscribing killing and prescribing treating others as one would like to be treated. Accordingly, nonviolence and peace are not rare, although they are rarely acknowledged, this despite the fact that there has been a progressively accumulating record of publications about them since at least the nineteenth century and especially over the last three decades. Biases in Western culture, and especially in American culture, tend to view humans as innately competitive and aggressive, thus neglecting if not completely ignoring nonviolence and peace.

Anthropology of Peace Founder

Ashley Montagu (1905–99) may be considered the founder of peace studies in anthropology. A humanist as well as a scientist specializing in biocultural anthropology, he was a prolific writer and prominent public intellectual. Montagu's (1976) *Nature of Human Aggression* is one of the earliest rebuttals of the genre of biological reductionism and determinism reflected in such pseudoscientific stereotypes as man the hunter, man the warrior, killer apes, beast within, and demonic males. He dismissed such stereotypes as 'the myth of innate depravity.'

Montagu compiled the first set of ethnographic case studies on nonviolent and peaceful cultures in the edited book *Learning Non-Aggression* with chapters about the Fore, !Kung San, Inuit, Semai, Australian Aborigines, Mbuti, and Tahitians. In the Introduction Montagu (1978: p. 5) lists the Punan, Hadza, Birhor, Todas, Veddahs, Arapesh, Yamis, Tikopia, Land Dayaks, Lepchas, Papago, Hopi, Zuni, and Ifaluk as additional nonaggressive societies. He observes that given the existence of such nonaggressive societies plus the wide range of aggression among other societies it is clear that aggression is not a biologically determined innate drive, but learned cultural behavior. Furthermore, he mentions that many nonliterate peoples have readily abandoned fighting, raiding, and warfare (p. 9).

Accumulating Documentation

Since Montagu's pioneering anthology of more than three decades ago, a substantial literature has been accumulating and advancing further documentation, including at least five sets of ethnographic case studies (Evans Pim, 2010; Fry and Bjorkqvist, 1997; Howell and Willis, 1989; Kemp and Fry, 2004; Sponsel and Gregor, 1994), four major monographs (Dennen, 1995; Fry, 2006; Kelly, 2000; Melko, 1973), an annotated bibliography (Bonta, 1993), and an encyclopedic Web site (Bonta, 2005). By now several hundred nonviolent and peaceful societies have been documented, and it is likely that many times more exist.

Beyond anthropology, especially noteworthy is the diachronic perspective provided by historian Matthew Melko (1973: pp. 34–35) who has identified 52 societies, mostly states, in the history of the world with periods of peace without any warfare extending over a century or more, and some as long as seven centuries. Melko (1973: p. 8) notes "It strikes me that any society chosen at random for any hundred years would experience far more peace than war. The examples of war and revolution are usually experiences of a few years at most in any century. And in those years, war is intermittent, and usually does not involve the whole society. If history is a history of war and revolution, that is because historians tend to focus on periods of violence and rapid change …. When we have finished observing man at his most violent and dynamic, the fact remains that generations have lived in peace, and people

and their leaders have managed to deal with their internal hostilities without recourse to war. Peace is a fact, not a vision. It is ubiquitous, incessant, normal. Peace prevails in most places at most times."

Returning to anthropology, beyond Montagu there are several outstanding pioneers in researching and documenting nonviolence and peace, and thereby in various ways refuting the unfounded presumption that there is some kind of biological drive inevitably generating aggression among humans universally and externally. David Fabbro (1978) wrote the early seminal article called 'Peaceful Societies' for the *Journal of Peace Studies*. Therein he asserted that absent in such societies is violence, war, external threat, social stratification, regular political leadership, police, and the military. Present is a small intimate community, egalitarian social structure, generalized reciprocity, group consensus in decision-making, and nonviolent values and conditioning.

Through more extensive cross-cultural research Bruce D. Bonta (1996: pp. 404–405) independently confirms Fabbro's attributes of nonviolent and peaceful societies and further elaborates on them. In their worldview, ethos, values, attitudes, practices, institutions, and customs such societies are fundamentally different from violent and warlike societies. This includes their perceptions of human nature, conflicts, dispute resolution, and intolerance of violence. Bonta asserts that peacefulness is a condition of human society characterized by a relatively high degree of interpersonal harmony; little if any physical violence; workable strategies for nonviolent resolution of conflicts and for averting violence; a commitment to avoiding violence with other societies; and strategies for the socialization and enculturation of children to adopt and continue nonviolent ways. He identified six strategies for the nonviolent resolution of conflicts: self-restraint, negotiation, separation for avoidance, intervention, meetings to reduce tensions, and humor. Bonta (1996: p. 414) observes "The basic reason for peacefulness in these societies is that people are strongly opposed to actual physical violence and firmly in favor of nonviolence…. Violence is never acceptable…. Peacefulness is an absolute commitment for them."

Semai

These attributes are illustrated in the specific case of the Semai of Malaysia. The Semai were studied first for more than 2 years by Robert Knox Dentan (1997) and subsequently for more than 2 years by Clayton A. and Carole J. Robarchek (1998). Independently they reached the same conclusions about the nonviolent and peaceful character of this society. The Semai themselves consider their own society to be nonviolent and peaceful, and likewise, every individual thinks of themselves in that way. Nonviolence is the ethos of their society, the pivotal organizing principle and focus. Physical violence of any kind terrifies any Semai person, they considered it to be senseless and stupid. Force is not returned with force, but only with passivity or withdrawal. The Semai say that they do not get angry and do not hit another person or fight. Nonviolence and self-restraint are pivotal social values learned from childhood. Children are never hit and see only nonviolent adults as their role models. Yet naturally some tensions and conflicts arise within a small community. If a dispute is pursued, then it may be resolved through compensation, by the community talking it through until concerns and emotions subside, or by requesting adjudication by respected elders. Social solidarity is maintained by recognition of mutual dependence, through cooperation and sharing, and by fear of dangers from external forces.

For more than a 100 years various outsiders have mentioned the abhorrence of violence by the Semai. Suicides and homicides are extremely rare, although higher estimates of homicide rates by authors other than the above ethnographers are bogus. However, outside of their own society a few Semai were recruited by the British during the early 1950s in counterinsurgency warfare against Communists wherein they were ordered to kill non-Semai and did so, but this is the only known exception of killing. Thereafter the Semai fighters returned to their village where they were reintegrated as nonviolent and peaceful individuals (Dentan, 1997: pp. 55–59, 133).

Natural History of Peace

In a chapter titled "The Natural History of Peace: A Positive View of Human Nature and Its Potential" Leslie E. Sponsel (1996) marshals evidence and arguments from the four subfields of anthropology to present the opposite perspective from innate depravity. His conclusions are as follows: (1) While conflict is inevitable and ubiquitous, violence is not. (2) Human nature has the psychobiological potential to be either nonviolent/peaceful or violent/warlike. (3) Nonviolence and peace prevailed in most prehistoric and nonstate societies. (4) War is not a cultural universal. (5) The potential for the development of a more nonviolent and peaceful world is latent in human nature.

In *Warless Societies and the Origin of War*, Raymond C. Kelly (2000) provides a most sophisticated and detailed analysis. He aims to develop a general model for the evolution of war that is grounded in cross-cultural comparison and tested against the archaeological record. Kelly (2000: pp. 121–124, 160) importantly observes "The origin of war is a question of enduring interest because the conclusions reached are of central relevance to our conceptions of human nature, and such conceptions inform the political philosophies that shape and legitimize our social institutions."

In Kelly's (2000: p. 10) view, the hallmark of the origin of warfare is not just capital punishment or blood revenge. Several generalizations emerge from Kelly's (2000: pp. 147–148) analysis: almost all early Upper Paleolithic societies lacked war; the earliest conclusive evidence of war is from Nubians around 14 000–12 000 BC; warfare was rare to absent until very late in human prehistory, around 7500–7000 BC; it was related to the development of farming with sedentary villages, thereafter competition over trade routes, and finally to states as centralized and hierarchical political organizations.

In Kelly's (2000: pp. 44–45, 56–57) analysis, nomadic foraging or unsegmented societies are warless. They have minimal social groups like the universal nuclear family and local community; no higher level of social organization nor any subunits; lack concepts of group liability; crucially avenge

murder does not lead to blood revenge feuding; group membership is fluid rather than fixed; and there is no food storage. In contrast, more sedentary or specialized forager societies have a segmented hierarchy and concepts of group injury, liability, and responsibility that combine to provide the basis for feuding or warfare (Kelly, 2000: pp. 46–48).

One of the foremost anthropological researchers on the subjects of nonviolence and peace is Douglas P. Fry. Through his numerous authored and edited publications for more than a decade he proves that humans are not innately warlike, but instead are fully capable of living in peace. Also he demonstrates that much of past scholarship has been biased by a presumption of a 'beast within.' Fry identifies the 'man the warrior myth' as the vacuous and unfounded assertion that war is ancient, universal, natural, normal, and inevitable. He argues that this assertion is irrefutably contradicted by reason and evidence. It reflects a cultural bias including Western assumptions about human nature; is an unconscious and unexamined assumption; results in selectivity and advocacy in the representation of war; and exaggerates aggression. It is careless thinking to define war so broadly as intergroup aggression and to conflate it with interpersonal violence and feuding.

Two antithetical models of human nature are identified by Fry. In the man the warrior model male competition for reproductive fitness generates belligerent militarism. His detailed critical analysis reveals the cultural bias, selective use of evidence, and muddled thinking involved in this model. The second model is the simple hunter-gatherer pacifist. Here natural selection generates nonviolent conflict management and helps maintains peace. The result of Fry's extensive critical analysis, his model is objective, systematic, holistic, and comparative.

Fry identifies factors that in various combinations facilitate conflict management in different societies: avoidance, tolerance, negotiation, self-redress, friendly peacemaking, mediation, arbitration, adjudication, and repressive peacemaking. He emphasizes that human adaptive plasticity and international governance can help generate more peace in the future. He recommends that peace may be advanced through extending nonviolent conflict management from within democracies to international relations; recognizing interdependence (economic, security, and environmental); cultivating crosscutting ties; and strengthening the United Nations and regional alliances (Fry, 2006). (For elaborations on aspects of his work and related subjects see Fry, 2013.)

Reexamining Tribal Warfare

One of the foremost anthropological students of warfare, R. Brian Ferguson, is among those who have called for a serious reconsideration of ethnographic representations of some cultures as engaged in chronic endemic warfare. In a book Ferguson coedited with Neil L. Whitehead (2000) ethnohistory and other lines of evidence demonstrate that much of what has been considered to be traditional 'primitive' or tribal warfare was actually generated at least in part by the external forces of colonialism. Even if warfare existed prior to colonial contact, often it was modified and intensified by such forces. These assertions potentially undermine much of the ethnological record of war along with the presumption that human nature is inevitably warlike.

In the particular case of the Yanomami Ferguson (1995) extended this provocative perspective in a most exhaustive, meticulous, and penetrating systematic study of the historical, ethnohistorical, and ethnological literature. He demonstrates that for centuries Yanomami have been influenced by the political economy of regional, national, and international systems, first directly on the periphery of their territory, and second indirectly spreading inward. He focuses mostly on intervillage conflict and violence generated by competition in situations of differential access to metal trade goods.

Another reconsideration of Yanomami warfare by Sponsel (1996, 2010b) systematically questions the scientific validity and utility of Napoleon A. Chagnon's (2012) depiction of their aggression. Furthermore, the analysis even questions whether Yanomami aggression can be realistically characterized as warfare rather than blood feuding with raiding as one tactic, a phenomenon more reminiscent of the famous historical case of the Hatfields and McCoys in Appalachia. This reexamination of Chagnon's ethnography also reveals that within his own description there is considerable information about nonviolence and peace among the Yanomami, even though it is mostly overshadowed by his obsessive fixation on aggression, the latter quite unlike any of the other more than four dozen anthropologists who have worked with the Yanomami, several for many more years longer. Thus, one of the commonly presumed classic documentations of tribal warfare is called into question, thereby also problematizing the stereotypical demonization of so-called 'primitive' peoples and human nature more generally.

Transformation from Killing to Nonkilling

From another angle, the Waorani in the Ecuadorian Amazon provide a most fascinating and significant case of the transition from a violent to a nonviolent society. Clayton and Carole Robarchek (1998a) conducted fieldwork among the Waorani who have long had a reputation for intergroup violence through a cycle of blood feuds with revenge raids. However, after the Waorani had been exposed by missionaries to the idea that a society could be nonviolent and peaceful, they adopted such ways surprisingly rapidly. This transition from a killing to a nonkilling society reveals the plasticity of human nature and domination of culture over biology. Also it emphasizes a society's cultural construction of its worldview, values, and attitudes, and how their practical consequences are manifest in behavior. In addition, the Robarchek's (1998b) have compared the traditional Waorani and Semai, noting that they are similar in their culture and ecology, except for their worldview which makes all of the difference. (The Dani of New Guinea made a similar transition as documented by Karl Heider, 1997: p. 172.)

Nonkilling

During recent years a largely new perspective has emerged in peace studies, one that is potentially revolutionary in its

ramifications. Political scientist Glenn D. Paige (2009: p. 127) in a pioneering book argues "The time has come to set forth human killing as a problem to be solved rather than to accept enslavement by it as a condition to be endured forever." He challenges the assumption that killing is an inescapable part of the human nature, the human condition, and social life. He goes beyond peace and nonviolence to focus sharply and objectively on killing because it is a more concrete and measurable attribute. Furthermore, Paige recognizes killing as the prime source and sustainer of other forms of violence, and he calls for liberation from killing through a shift from the politics of killing to the those of nonkilling.

Paige poses the pivotal and provocative question: Is a nonkilling society possible? He defines a nonkilling society as a human community from the local to the global levels characterized by the absence of killing of humans, threats to kill, weapons designed to kill, justifications for using them, and conditions of society dependent upon the threat or use of lethal force for maintenance or change (Paige, 2009: p. 21).

From the previous discussion in the present article the answer to Paige's primary question is obviously in the affirmative. Indeed, clearly not only is a nonkilling society possible in theory, it exists in reality in several hundred societies as documented by numerous and diverse anthropologists, some as in the case of the Semai, independently affirming through their fieldwork with the same society that it is nonkilling. However, this does not mean that interpersonal violence is totally absent in all of these cases, but that it is so rare as to be virtually so.

Paige's underlying thesis is that humans are capable of both killing and nonkilling; most humans are not killers (99%); nonkilling capabilities already work in a wide range of social institutions; and the capability exists for nonkilling transformative interventions. Accordingly, he problematizes the very foundational acceptance of violence in political science, politics, government, and society. He calls for objective scientific and scholarly investigation of the possibilities and actualities of nonkilling.

Another aspect of Paige's (2009: pp. 73–74, 79, 88–89) book is the four-part logic of analysis: What are the conditions, causes, and consequences of killing, nonkilling, and the transition from one to the other in either direction? Within the anthropology of peace studies, the ethnographic cases previously mentioned in the present article of the Yanomami, Semai, Waorani, and Dani are seminal examples coinciding with components of this mode of analysis. Far more systematic and objective empirical research is sorely needed to document in detail the varieties of nonviolent and peaceful societies throughout the world as well as transitions from violence and war to nonviolence and peace, or the converse. Bonta's (2005) Web site on peaceful societies is a prime resource to commence such research.

Expanding on the idea of a peace-to-war continuum of Karolina Baszarkiewicz and Fry (2008: pp. 1560–1561) can help to transcend some of the problems that arise from identifying a society as either killing or nonkilling, as, for example, when killing occurs but rarely in an otherwise nonkilling society, or when most individuals in a killing society do not kill. It may help to envision both intrasocietal and intersocietal variation along this continuum between the polar extremes of nonkilling and killing recognizing that most societies fall somewhere along this continuum, but that their position may shift in either direction. This idea of a continuum surmounts problematic absolutist and essentialist thinking in terms of either-or, all-or-none, always-or-never.

Apologists for War

In various ways some anthropologists and others appear to be apologists for war in the sense that ultimately they blame some ethereal human nature as an excuse rather than recognizing the primacy of the specific political and moral choices that are decisive. Archaeologist Lawrence H. Keeley (1996) in his book *War Before Civilization*, primatologist Richard Wrangham with Dale Peterson (1996) in *Demonic Males: Apes and the Origins of Human Violence*, and archaeologist Steven A. Le Blanc with Katherine E. Register (2003) in *Constant Battles: The Myth of the Peaceful, Noble Savage* are anthropological examples of a genre arguing that war is ubiquitous in time and space as a manifestation of human nature (cf Sponsel, 2012: pp. 21–30). Furthermore, they assert that the psychobiology of *Homo sapiens* inevitably generates territoriality, competition, hostility, violence, and warfare within and between human societies. In the guise of science and scholarship this political ideology celebrates the man the warrior model wherein the predator naturally turns inward to prey on its own kind thereby becoming the premier killer ape.

Keeley, for example, aims to expose and rebut the supposed 'pacification of the past' by liberal anthropologists. However, he carelessly defines war so broadly as to be meaningless; neglects the substantial literature irrefutably documenting nonviolent and peaceful societies; ignores the very serious limitations of the archaeological evidence from prehistory; and constructs blatantly biased interpretations of 'data.'

This mind-set has persisted since journalist Robert Ardrey's books *African Genesis* (1961) and *Territorial Imperative* (1966), and for that matter, with Thomas Hobbes (1651) *Leviathan* and long before. Psychoanalyst Sigmund Freud (1930) in *Civilization and Its Discontents* and ethologist Konrad Lorenz (1966) in *On Aggression* contributed to this mind-set as well in both the scientific and public arenas.

Most recently the essence of this perspective is exhibited in biologist Edward O. Wilson's (2012) *The Social Conquest of Earth* in the chapters revealingly titled "Tribalism Is a Fundamental Human Trait" and "War as Humanity's Heredity Curse." He equates tribalism with universal 'groupist behavior' which is some vague kind of presumed hardwired or inborn tendency for in-group social identity inexplicably automatically correlated with its territoriality, hostility, and aggression toward any out-group. Wilson (2012: p. 62) asserts "Our bloody nature, it can now be argued in the context of modern biology, is ingrained because group-versus-group was a principal driving force that made us what we are. In prehistory, group selection lifted hominids that became territorial carnivores to heights of solidarity, to genius, to enterprise. And to *fear*. Each tribe knew with justification that if it was not armed and ready, its very existence was imperiled. Throughout history, the escalation of

a large part of technology has had combat as its central purpose." Then Wilson (2012: p. 65) reveals "It should not be thought that war, often accompanied by genocide, is a cultural artifact of a few societies. Nor has it been an aberration of history, a result of the growing pains of our species' maturation. Wars and genocide have been universal and eternal, respecting no particular time or culture."

Wilson's reasoning may be a logical construction, but it is a speculative 'just so story' reminiscent of nineteenth century evolutionists devoid of any convincing proof and acknowledgment of the substantial contrary scientific evidence sampled in this article. This is simplistic and reductionistic biological determinism. Such gross generalizations are contradicted by the tremendous variation within and among societies from prehistory to the present. If some kind of an instinctive drive for aggression actually existed as imagined by Wilson, then far more violence including warfare would exist as well, yet 99% of humanity has never killed anyone.

It is especially relevant here that there is significant evidence from psychology contradicting the demonic male and related speculative models. Military personnel have to be trained systematically to kill, it does not come naturally. In spite of training, including desensitizing the soldier and dehumanizing the enemy, most military do not kill, even on the battlefield. Only about 20% of combat soldiers even fire their weapons. Those who do kill often suffer lingering emotional problems thereafter, in many cases posttraumatic stress disorder. Shooting can be more traumatizing than being shot. Surprisingly, even operators of drones (unmanned aircraft) that kill humans from a distance may suffer emotionally. Ordinarily there is a natural inhibition against killing another human. Indeed, the case can be made that selective pressures facilitated nonkilling in the course of human evolution as a successful adaptation (Evans Pim, 2009: pp. 327–340, 359; Fry, 2006, 2013).

Fry very usefully discusses in detail seven ways that evidence of nonviolent and peaceful societies is disputed, denied, or ignored: "l. Stridently emphasize violence and simply ignore all evidence to the contrary …. 2. Set an impossible standard, such as requiring a peaceful society to be absolutely and totally free of all forms of aggression across time, find a few real or apparent exceptions to the impossible standard, and then dismiss the society in question as clearly NOT peaceful …. 3. Count any type of conflict as if it were aggression …. 4. Cite an inflated homicide rate to exaggerate violence …. 5. Regarding warfare in particular, make clever use of terminology to exaggerate the number of societies that engage in war …. 6. Apply cases of violence or war from a certain place or time to a totally different place or time …. 7. Create a bogus peaceful society, then destroy your creation" (Kemp and Fry, 2004: pp. 185–204). (Also see the chapters by Piero P. Giorgi, Leslie E. Sponsel, and Robert W. Sussman and Donna Hart in Evans Pim, 2010.)

When the very substantial evidence for the natural history of peace that has been accumulating for well over three decades as highlighted in the present article is totally ignored by apologists for war and others, then the only logical conclusion is that either the author is entirely unaware of the relevant literature and thus has failed to pursue adequate research to provide a fair and balanced approach, or the author is disingenuous in avoiding contradictory data and arguments. Either of these two deficiencies is irresponsible and unworthy of the designation science or scholarship. Moreover, in some situations privileging the study of war and other forms of violence to the complete exclusion of any consideration of nonviolence and peace might tend to legitimize and celebrate violence and war, and thereby might indirectly facilitate them even if inadvertently.

More Obstacles

There is a systemic bias privileging attention to, and often pursuit of, violence and war in Western culture, and especially in America. It is a product of the industrial–military–scientific–academic–media complex, especially in the U.S.A. It reflects some variants of Abrahamic religions as well. Science and scholarship are not necessarily entirely apolitical and amoral, but can be biased by culture, religion, ideology, politics, and/or personality.

This systemic bias is an empirical fact that can be demonstrated quantitatively in the public, academic, peace studies, and anthropology arenas. For instance, on 16 October 2012, a search of Google.com for these key words revealed the following: violence 387 000 000; nonviolence 5 380 000; war 2 480 000 000; and peace 922 000 000. In a survey of articles in *the Journal of Peace Research*, Hakan Wiberg (1981) found that from 1964 to 1980 there were 400 articles, but only one on peace, the previously mentioned one by Fabbro (1978). As a more recent example, in the *Encyclopedia of Violence, Peace, and Conflict* (Kurtz, 2008), out of a total of 289 entries, only 10 (3.5%) are on nonviolence while only 29 (10%) are on peace, the rest focused on various aspects of violence and war. In the case of anthropology, a search on 16 October 2012 of the Anthropology Index Online revealed the following number of citations for journal articles from 1950 to 2012 for these key words: violence 2789; nonviolence 2; war 10 000; and peace 608. It should be cautioned that not all of the citations found are relevant to the key words. Furthermore, the citations that appear under peace are overwhelmingly about conflict, violence, and/or war.

This striking discrepancy is troubling because it is impossible to achieve a more nonviolent and peaceful society by ignoring these phenomena. To use an analogy, health and illness are necessarily complementary concepts. Exclusively studying only disease is insufficient, if the concern is with health, and the converse holds as well. Furthermore, when the components of nonviolence and peace in a society are neglected, then reality may be distorted to the point of being misleading and that may have serious practical consequences (Sponsel, 1998, 2010a,b).

This systemic bias can discourage concerns for peace and peace activism. If war is an inherent tendency in human nature, then it seems to be inevitable, unalterable, and unavoidable. Such a mind-set may contribute to some government leaders privileging military over diplomatic resolutions of conflicts, pursuing an arms race, spending excessive amounts of money on weapons instead of other matters like medical research and education, considering preemptive strikes, and so on (cf Fry, 2006: pp. 251, 262).

Another obstacle is that many authors writing about war and peace pursue the negative concept of peace as no more than the absence of war. The focus is on direct violence, violent resolution of conflict, war as natural, defense of nation, and superficial symptoms rather than ultimate causes, a realist purview. In contrast, the positive concept of peace is far more inclusive. It encompasses the presence of human rights, defense of humanity, indirect or structural violence, the ultimate causes of violence and war, nonviolent conflict resolution, and peace as natural, a liberal purview. Peace is more than simply the absence of war, just as life is more than simply the absence of death (Sponsel and Gregor, 1994: pp. 1–36).

Ultimately much of the above also reflects a fundamental difference in political ideology despite the overt pretense by most scientists of being apolitical and amoral. The realist or conservative tends to pessimistically view humans as evil and driven by selfish instincts; international politics as competition for power and national interests; war as inevitable; everything as subordinated to national interest; defensive strength as necessary to subdue or deter enemies; and violence as the means to resolve conflicts. On the other hand, the liberal or leftist tends to optimistically view humans as good; altruism as natural; international politics as cooperation for mutual interests and principles; peace as inevitable; national and international interests as often coinciding; international associations as pivotal; and nonviolent resolution of conflicts as the most desirable and effective (Kegley and Raymond, 1999: pp. 20–21, 245). Of course, individuals and groups may not neatly fall into one category or the other depending, on the specific issues involved.

Conclusions

Nonviolence and peace are ubiquitous, violence and war are not. There are societies that do not have warfare, and where homicide and other forms of violence are extremely rare or totally absent. Furthermore, there is tremendous variation in the manifestation of violence, nonviolence, war, and peace among some 7000 cultures in the world today which renders facile generalizations about human nature untenable. Even those societies wherein interpersonal or intergroup aggression is manifest in various ways and degrees, it is not ubiquitous simply because for any society to survive there are indispensable attributes like sociability, cooperation, reciprocity, altruism, and empathy that strongly discourage any regular violence and war. If nonviolence and peace are not taken into account, then considerations about human evolution, human nature, the human condition, cultures, regions, culture history, and conflicts may be incomplete and may misinform and mislead.

The Semai, Yanomami, Waorani, and Dani cases are especially pertinent to the anthropology of peace and nonviolence. All four are small-scale indigenous societies pursuing a subsistence economy in mountainous tropical forest ecosystems in three widely separate geographical areas. Such societies may be considered to be among the most basic expressions of human nature, yet they are very different with respect to violence, nonviolence, war, and peace. Their differences are not explicable in terms of biology or other aspects of 'nature' but only in terms of 'nurture' which means culture. For instance, if their differences were attributable to some fixed biological aspect of human nature, then this would not allow the abrupt, willing, and definitive transition from violence and war to nonviolence and peace in the case of the Waorani and Dani among many others.

Many problems and issues are discussed and debated in the anthropological literature on peace studies, among them: the antiquity, universality, and inevitability of war versus peace; biological versus cultural explanations of the causes and effects of war and peace, the biological including sociobiology and its successor evolutionary psychology, the cultural with materialistic versus mentalistic explanations; tribal warfare compared with that of states; and the impact of states on aggression within and among tribes. In any case, nonviolence and peace surely merit just as much serious, systematic, and empirical attention as violence and war, if the aforementioned biases can be surmounted by those anthropologists and others who identify themselves as objective scientists and scholars. Paige (2009:126) asserts that every individual can be a center for global nonkilling to facilitate the transition to a nonkilling world. This applies to anthropologists as well as to both their teaching and their research.

Peace Keeping

Franz Kernic, ETH Zurich / Swiss Federal Institute for Technology Zurich, Zurich, Switzerland

Abstract

Peacekeeping can be understood as a measure to limit and manage armed conflict and political violence. Its main goal is to assist societies and states in the transition from war to peace and to prevent a potential escalation toward war. Since 1948, the United Nations and other actors have conducted more than 100 peacekeeping operations around the globe. In the 1990s, the concept of peacekeeping was further developed and expanded. New missions were launched leading to a tremendous increase in the number of operations and peacekeepers deployed and a wide array of different operations in terms of mandate, scope, size, duration, and troop composition. New theories and concepts started to emerge at the turn of the millennium, contributing to a broader understanding of peacekeeping and linking it closer to ideas of liberal peace, democracy, and development.

Introduction

Peacekeeping is commonly understood as a tool to manage and resolve armed conflict and political violence and to assist societies in the transition from war to peace. Although the basic idea can be traced back further in history, the term itself came into use in the 1950s in association with the United Nations' conflict management efforts in global politics. At the early stage, peacekeeping was regarded as a measure to be taken in the aftermath of war in order to assist the implementation of a peace agreement and to lay the groundwork for conflict resolution and a peaceful settlement of the conflict. Since the 1990s, a few peacekeeping operations have also been set up specifically for the purpose of conflict prevention. Over the last 60 years, the concept of peacekeeping has been modified and expanded significantly. Changes in global environment and international system have stimulated both the emergence of new types of peace operations and attempts to conceptualize and design them. This development has led to today's wide spectrum of definitions and concepts, as well as different practical arrangements for peacekeeping.

Reviewing the existing definitions and concepts of peacekeeping, one quickly comes to the conclusion that there is in fact little agreement among scholars and theorists as to what peacekeeping is beyond the fact that the term itself refers to activities that help create conditions for conflict resolution and sustainable peace. Every scholar attempting to define peacekeeping is confronted with the fact that there are a number of commonly used terms with blurry boundaries: peace-building, peacemaking, peace-enforcement, peace-support, etc.; terms that, in common language, are frequently used interchangeably to refer to very similar activities and phenomenon. An additional difficulty emanates from the fact that, due to its specific connotations, the term peacekeeping is often used by governments to label and legitimize political action that in fact has nothing to do with the original peacekeeping idea and frequently only helps to cover up conventional military intervention. Finally, it must also be noted that, in recent years, the term peacekeeping has been incorporated into, or even merged with, the broader term of 'peace operations.'

Since the early years of the Cold War, the UN and other actors have conducted more than 100 peacekeeping operations in the field, ranging from large-scale troop deployment to small-size missions and significant variations in terms of scope, mandate, duration, and composition. The UN in particular has taken on a key role in conceptualizing peacekeeping as an instrument for the settlement of armed conflict, the construction and maintenance of peace in war-torn societies, and in establishing and deploying peacekeeping forces around the world. As of July 2012, the UN is the world's largest multilateral contributor to international peacekeeping and postconflict peace-building, deploying approximately 97 000 uniformed personnel (troops, military observers, and police) from 119 countries in 16 UN-led peace operations on four continents (UN Peacekeeping Fact Sheet, 2012). This impressive number represents a tremendous increase in both UN operations and UN peacekeepers since the year 1989. During the Cold War era, the number of both UN peacekeeping missions and peacekeepers was significantly lower. Since the first Cold War UN missions, both theory and practice of peacekeeping have changed dramatically, and the nature and scope of the operations, their specific role in global politics, and their impact on conflict management and resolution in modern societies have been significantly altered too.

Theories and Concepts

Of course, all theories and concepts of peacekeeping need to be seen as embedded in the much broader context of our prevailing political and social theories, particularly our theories of international relations and peace and conflict. Major changes and paradigm shifts in those theories have a significant impact on how peacekeeping is defined and conceptualized. In the last few decades, a number of new theoretical approaches in the social sciences and behavioral studies have contributed to a comprehensive reevaluation of our prevailing concepts of peacekeeping and their respective key assumptions, thus enriching the scientific study of peace operations from multidisciplinary perspectives.

To begin with, it is important to note that the UN's attempts to develop a conceptual framework for its peacekeeping efforts and for systematically dealing with security and transition issues in the aftermath of war and violent conflict have always suffered from the fact that the term 'peacekeeping' is not found in the UN Charter. Nevertheless, references have often been made to a nonexisting 'Chapter six-and-a-half,' meaning that the Charter still needs to be seen as providing a legal and normative framework for such operations that could, theoretically, be placed right in between the arrangements outlined in Chapters VI and VII. The UN has never overcome this deficit and even today the organization is still struggling with the problem of clearly stipulating the meaning of peacekeeping. Not surprisingly, member states have continued to express different views on how to translate the basic idea of peacekeeping into concrete action in the field and to define precisely what one could write down and commonly agree on in such a Chapter Six-and-a-half.

Nevertheless, the UN did manage to quickly achieve a minimum consensus about a few basic principles of peacekeeping, thus opening the door for launching and managing a number of UN operations and making the necessary practical arrangements. First, there was general agreement among member states about the utility of peacekeeping for conflict management, and that it was desirable to use this tool within the UN system and under specific circumstances to limit the incidence of armed conflict, to implement peace accords, and to assist societies and states in the transition from war to peace (particularly if the conflicting parties request such an assistance). Second, there was also a broad consensus that peacekeepers could and should carry out some essential tasks needed to facilitate such a peace process (e.g., monitor ceasefire, observe peace processes and report violations of peace accords, apply confidence-building measures, provide administrative and logistic support, etc.). Third, close collaboration with diplomatic efforts toward conflict resolution seemed highly desirable, thus also prompting the idea of peacekeepers as 'diplomats in uniform.' Finally, there was widespread acceptance of the following three core principles of peacekeeping: consent, impartiality, and minimum use of force. In this respect, Canadian diplomat Lester B. Pearson and Dag Hammarskjöld from Sweden, who served as UN Secretary-General from 1953 to 1961, are generally given much credit for coining the term and for conceptualizing peacekeeping, together with promoting ideas of preventive diplomacy and collective security.

Most common definitions of peacekeeping are either linked to this original idea and the three outlined key principles (UN DPKO, 2008: 31–35) – frequently focusing on the 'functions' of peacekeeping – or they tend to emphasize more the specific 'tasks' that peacekeepers – the military, police, and civilian personnel – have to accomplish (e.g., UN DPKO, 2003: 1–2). Frequently, nonengagement in combat, i.e., the use of force being strictly limited to self-defense, is stressed as an important characteristic. But precisely this issue has always been very controversially discussed, particularly due to the fact that it is extremely difficult to draw a clear line between peacekeeping and peace-enforcement. As early on as the 1960s, the UN became very much aware of the potential for escalation and the danger that a peacekeeping operation suddenly might be forced to exceed its original mandate and engage in combat (e.g., the experience of UN peacekeeping mission to the Congo, 1960–64).

The big differences in composition and conduct of peacekeeping operations over the last 60 years have encouraged scholars to develop certain 'typologies.' For example, Bellamy and Williams (2010) developed a typology based "on the type of actors that conduct them (i.e. individual states, coalition of the willing, or formal regional arrangements and other international organizations) and their relationship to the UN (i.e. whether they are UN 'blue helmet' operations, UN-authorized operations or non-UN operations)" (Bellamy and Williams, 2010: 43f). Others tended to differentiate between various 'generations' of peacekeeping, each generation representing a different type of operation and nature of peacekeeping: First-generation peacekeeping (or traditional, prior to 1988), followed by second-generation peacekeeping (multidimensional and more complex operations, large in size, far-reaching objectives), third-generation peacekeeping (since the late 1990s, large-scale and robust 'peace support operations'), and, finally, fourth-generation peacekeeping (since the mid-1990s, subcontracting the military component). However, if seen in strict chronological order, this approach is misleading. It appears more appropriate to see a general widening of peacekeeping over the years, thus allowing a parallel existence of all generations, although with shifting priorities and weights.

This changing nature of peacekeeping was already addressed in Boutros-Ghali's *An Agenda for Peace* (1992), stating that "the established principles and practices of peacekeeping have responded flexibly to new demands of recent years, and the basic conditions for success remain unchanged: a clear and practicable mandate; the cooperation of the parties in implementing that mandate; the continuing support of the Security Council; the readiness of Member States to contribute the required military, police and civilian personnel, including specialists; effective United Nations command at Headquarters and in the field; and adequate financial and logistic support" (paragraph 50). This document also provided a definition of peacekeeping, distinguishing it from other terms such as 'preventive diplomacy' and 'peace-making': "*Peace-keeping* is the deployment of a United Nations presence in the field, hitherto with the consent of all the parties concerned, normally involving United Nations military and/or police personnel and frequently civilians as well. Peace-keeping is a technique that expands the possibilities for both the prevention of conflict and the making of peace" (paragraph 20).

Paradigm shifts in international relations theory have heavily influenced the way peacekeeping is conceptualized. While realism tended to emphasize the role of states in global politics and, consequently, with respect to peacekeeping, to focus primarily on the possibilities and conditions for a peaceful settlement of disputes between states (taking a specific state-centered or 'Westphalian view' of the international system), the emergence of new ('post-Westphalian') concepts of liberal peace gave birth to a quite different perspective on the purpose and utility of peacekeeping. In the 1990s, many scholars and politicians saw the spread of liberal democracy as the best path to global security and peace. Consequently, new concepts of peacekeeping emerged that

were significantly broader than before, focusing much more on how to create, spread, and maintain liberal democracies and promote an agenda for sustainable peace than on limiting and managing armed conflicts between or inside states. This paradigm shift brought peacekeeping much closer to the political agendas of development, humanitarian assistance, rule of law, and public security.

In the early twenty-first century, these concepts of a 'widened' or 'enlarged peacekeeping' were increasingly met with skepticism and sometimes radically called into question. Some emerging new theories (for example, critical theory and globalization theory) took on a rather critical stand when evaluating peace operations and their long-term impact on modern societies. In this context, new questions were raised, such as whether it is the international community that decides autonomously where and how peace operations are conducted or autonomous processes of 'globalization' and/or a specific 'global culture' (Paris, 2003) that force states to act in a specific manner and to apply the available peacekeeping instrument according to certain 'structural needs.' Critical theory, in turn, has drawn our attention to issues of control, disparity, and social struggle in the global economic system, and the problem of economic hegemony, opening the door, for example, for Michael Pugh's argument that "peace support operations serve a narrow, problem-solving purpose – to doctor the dysfunctions of the global political economy within a framework of liberal imperialism" (Pugh, 2004: 39). According to him, the limits of the post-Cold War forms of peacekeeping lie in "the inherent contradictions of a capitalist hegemony trying to keep the lid on instability" (Pugh, 2004: 53). In recent years, such critical voices have given rise to a number of new proposals for a radically reconceptualized peacekeeping. Among them, the idea of 'cosmopolitan peacekeeping' has gained considerable influence (Woodhouse and Ramsbotham, 2005).

UN and Non-UN Peacekeeping

Although the UN has become one of the primary peacekeeping actors in global politics since the early 1950s, it has never been the only actor conducting peacekeeping operations. In their study, Heldt and Wallensteen (2006) even argue that "in terms of number of operations and personnel," non-UN "activities are fully comparable to the UN's efforts" (39): "At the aggregate level there is a strong relationship over time between the number of ongoing peacekeeping operations carried out by the UN and non-UN actors, and an even stronger one for these actors' operations in intrastate conflicts, while virtually none exists for deployment in interstate conflicts" (Heldt and Wallensteen, 2006: 39). In particular, regional organizations, such as the Organization of American States, Economic Community of West African States, Organization of African Unity (OAU) and African Union (AU), North Atlantic Treaty Organization (NATO), and the European Union (EU), have played a much more active role in peacekeeping around the globe in the last two decades; but also single states and state coalitions ('coalitions of the willing') have become important peacekeeping actors, sometimes explicitly authorized by the UN Security Council. The UN Charter gives the UN Security Council the power to authorize regional organizations or other coalitions to conduct peacekeeping operations on its behalf, but it is important to note that the record of peacekeeping operations during the Cold War and post-Cold War era includes several actions that obviously lack such authorization.

From the early 1950s onward, one central problem of UN peacekeeping has been related to an obvious lack of resources and force capabilities to carry out these tasks and being permanently at the disposal of the organization. The UN still has no standing military forces – despite the existence of respective provisions in UN Charter Articles 42 and 43 – so that ad hoc UN troops for every mission and task are to be established. This, in turn, has made UN peacekeeping highly dependent on the willingness of its member states (and others) to provide the necessary troops, material resources, and funds. In this context it is worth noting that some of the weaknesses of the UN – with its unique attempt to balance power among major powers and member states – have had a negative and hampering impact on the way the organization organizes and conducts its daily business, including peacekeeping. Several shortfalls have been identified over time, thus leading to various internal reforms and attempts at strengthening both the conceptualization and design as well as the practical handling of peacekeeping operations. Two milestones in this respect, the Brahimi Report 2000 and the Peace Operations 2010 Reform Agenda, have stimulated an intense public debate about the future direction of UN peace operations and the proper use of this instrument in global conflict management.

The UN has an impressive record of peacekeeping activities: As of July 2012, the organization has conducted a total of 67 peacekeeping operations since 1948, with 16 operations ongoing; and more than 100 countries have provided military, police, and civilian personnel (UN Peacekeeping Operations Fact Sheet, 2012). The numbers of UN peacekeeping operations and UN peacekeepers deployed have significantly changed over time, with a first peak in the early 1990s (78 444 troops, police, and military observers in July 1993) and a second peak in the year 2010 (101 393 troops, police, and military observers in March 2010) (UN DPKO Statistical Material, 2012a). The total number of fatalities in those missions comes to slightly more than 3000 (1948–2012) (UN DPKO Situation Center, 2012) (for additional statistical material and data, see Heldt and Wallensteen, 2006; Bellamy and Williams, 2010).

In addition to UN peacekeeping, non-UN actors have conducted a number of similar operations that can be considered peacekeeping in terms of their mandate and scope. The list is lengthy and includes both large-scale (for example, the 'Indian Peace Keeping Force,' in Sri Lanka, 1987–90, had a size of more than 50 000 soldiers) and quite small operations. Since the mid- and late 1990s, several regional organizations have taken on an active role in planning and setting up new peacekeeping operations; among them the EU, which incorporated the so-called 'Petersberg tasks' of the Western EU (1992) into its Common Foreign and Security Policy, thus identifying peacekeeping as one of the Union's key security and military tasks. In recent years, the AU has started to build up its own peacekeeping capabilities and to conduct its own operations in Africa (e.g., African Union Mission in Sudan, 2004–07; African Union Mission in Somalia, since 2007). The EU has financially contributed to this development and concluded

a comprehensive 'Africa-EU Peace and Security Partnership' in order to strengthen regional security in Africa and to enhance the AU's capabilities to lead and conduct simultaneously multiple peacekeeping operations on the African continent.

The historical perspective allows us to identify a few interesting patterns and trends in UN peacekeeping:

- First, a significant shift in terms of troop-contribution has occurred since the first UN peacekeeping operation was set in motion. During the Cold War, European states dominated UN peacekeeping. However, since the early 1990s, South Asian (Pakistan, Bangladesh, India, Sri Lanka, and Nepal) and African states (Ghana, Nigeria) have become the largest troop providers to UN peace operations – a trend that has continued until today. Countries such as Bangladesh, Pakistan, India, Ethiopia, and Nigeria currently (July 2012) shoulder the greatest burden and provide a huge number of personnel to the UN, while the troop-contribution of Western countries – Europe and the United States – are on decline, counting only for about 5% of the personnel deployed in UN peacekeeping operations (UN DPKO Statistical Material, 2012b; compare Bellamy and Williams, 2010: 147).
- Second, the composition of UN peacekeeping troops has always tended to be multinational and comprising soldiers, police officers, and civilian personnel, although with a strong majority of military personnel. In this respect, the available data (UN DPKO Statistical Material, 2012c) point to an increase in the number of police officers deployed in UN missions, thus also indicating the increasing importance of policing and rule-of-law tasks in those operations.
- Third, specific procedures and arrangements were established in order to avoid some of the pitfalls and risks of peacekeeping. Many of them have proved crucial with respect to mission success and maintaining political control over the practical management in the field, including, for example, the provision that UN peacekeeping operations are mandated for a short period of time only (in general a 6-month period).
- Fourth, despite fluctuation in the number of peacekeeping operations and peacekeepers deployed, it is important to note two important trends: First, there are significantly more peacekeepers deployed in the post-Cold War period than before during the Cold War era. Second, the number of peacekeeping operations – both UN and non-UN – has also significantly increased after 1989 (Human Security Report, 2009/10: 70, Figure 4.3).
- Finally, it is remarkable that the peacekeeping operations have never been equally distributed among the continents and regions. There was a strong regional bias in the Middle East and only few UN missions were deployed in Europe, Africa, and the Americas during the Cold War. In the post-Cold War era this focus shifted, showing a significant increase in UN peace operations in Africa and Asia.

The Historical Development

Although instances of peacekeeping can be traced further back in history, particularly the nineteenth and early twentieth centuries (e.g., the deployment of a Swedish-Norwegian peace force to Schleswig 1849–50; the deployment of a League of Nations peacekeeping force to the Saar region), peacekeeping as a political instrument for global conflict management started to systematically develop with the UN's activities during the early years of the Cold War. The design, setup, and conduct of the first UN missions need to be seen as an important step toward establishing peacekeeping as a measure to be taken by the international community to limit and manage armed conflict in the bipolar and highly confrontational international environment of the Cold War period. In 1948, the UN had to deal with two major conflicts where diplomatic efforts were deemed highly necessary in order to maintain peace and security: Palestine and Kashmir. Interestingly, the two UN peacekeeping operations established at that time to manage those two conflicts and to oversee ceasefire agreements turned out to be not only the organization's first such operations, but also those which have lasted the longest (UN Truce Supervision Organization, 1948–present; United Nations Military Observer Group in India and Pakistan, 1949–present).

The first UN operations also served as role models for other similar arrangements, i.e., they helped to institutionalize certain mechanisms and procedures for putting together a peacekeeping mission. When confronted with the need to deal successfully with the Suez crisis, the UN further developed its peacekeeping concept and gradually adopted a common view on how ad hoc missions could be integrated into a broader concept of preventive diplomacy, thus allowing the UN from then on to take on a more decisive and coherent role in global conflict management. The UN operation in Sinai (United Nations Emergency Force I, 1956–67) turned out to be crucial in this respect. Despite the fact that different views and ideas about the proper use of this instrument continued to exist, the UN managed to authorize a number of additional peacekeeping operations until the end of the Cold War. Not surprisingly, numerous modifications and adaptations had to be made, resulting in a wide spectrum of different types of operation with sometimes quite different characteristics.

There were a total of 15 UN peacekeeping missions conducted from 1948 to 1988 (UN DPKO Statistical Material, 2012d) with a strong regional bias in and focus on the Middle East. However, tensions during the Cold War sometimes made consensus among major powers and member states extremely difficult. The role of the UN in global conflict management therefore remained highly contested. In the 1980s, the utility of peacekeeping operations as a tool for conflict management was increasingly called into question, thus leading to a period of stagnation in terms of practical arrangements and scope of UN peace operations. The largest and most complex operation during the Cold War period was conducted in the former Belgian colony of the Congo (United Nations Operation in the Congo, 1960–64) where troops engaged in combat.

A tremendous boost to UN peacekeeping happened immediately after the end of the Cold War. A number of new, larger, and more complex missions were authorized by the Security Council, increasingly also incorporating civilian tasks (like monitoring elections) into the mandate. Africa became a region with an increased demand for peacekeeping, with peacekeeping operations to be established in Angola, Western

Sahara, Somalia, Mozambique, and Uganda–Rwanda, but also Asia (e.g., in Cambodia) and Central America entering the spotlight of the UN's conflict management. This period also witnessed an increased participation of Western great powers in peace operations, e.g., the U.S. engagement in Somalia. The experiences in those operations led to new debates about the minimum use of force principle and the proper boundaries between peacekeeping and peace-enforcement.

Bellamy and Williams (2010: 93) speak about a 'triple transformation' that occurred with respect to peace operations during the 1990s, consisting of a quantitative, normative, and qualitative dimension. The authors emphasize that there was not only a radical increase in numbers of missions and troops deployed, but also a gradual normative shift and a new quality of peacekeeping in the nature of how these operations were conducted and which tasks were assigned (Bellamy and Williams, 2010: 100). In fact, the numbers of peacekeepers deployed around the globe peaked in the early 1990s and the number of missions that were authorized between 1988 and 1993 came to a total of 20 (Bellamy and Williams, 2010: 95). However, a tremendous setback happened only a few years later as a consequence of two major failures of UN peacekeeping, the Rwandan genocide (1994), and the massacre in Srebrenica and Bosnia-Herzegovina (1995). Both events – in combination with other failures such as in Somalia and Angola – led to a very controversial international debate about the utility of peacekeeping for limiting and managing conflict in the new post-Cold War world order, i.e., a period of reevaluation and general decline in peacekeeping efforts.

This development cumulated in a number of new ideas on how to strengthen peacekeeping and to avoid the pitfalls of past experiences. The obvious failures of the mid-1990s immediately led to a reduction in the number of UN peacekeepers. The number of troops deployed dropped from about 70 000 in 1993 to approximately 20 000 in 1996 (UN DPKO Statistical Material, 2012a), the UN facing a certain reluctance of its member states with respect to troop-contribution. However, this trend did not continue and, on the contrary, the numbers of operations and troops significantly increased again after the turn of the millennium. The first decade of the twenty-first century witnessed a 'limited rebirth' of UN peacekeeping and increased peacekeeping efforts of regional organizations. Two major operations were launched around 1999–2000: one in Kosovo (the NATO-led international peacekeeping mission of the 'Kosovo Force,' under UN mandate and the United Nations Interim Administration Mission in Kosovo) and the other in East Timor (the International Force for East Timor, a multinational peacekeeping operation under UN mandate, and the United Nations Transitional Administration in East Timor, which was succeeded by the United Nations Mission of Support in East Timor, in May 2002); and two smaller missions were authorized (Sierra Leone and Democratic Republic of the Congo). The number of peacekeepers doubled again and Africa became a region with increased and intensified peacekeeping efforts from both United Nations and other regional organizations. The following years saw a steady increase in the number and size of UN peace operations, peaking in 2010 with slightly more than 100 000 uniformed personnel being deployed and a slight decline in the following years (UN DPKO Statistical Material, 2012e).

The Study of Peacekeeping Operations

Since the 1950s, a wide array of theories and concepts has been developed in order to understand peacekeeping and to explain certain peculiarities of specific missions. The growing number and range of peace operations during the 1990s has stimulated further empirical research, as well as a number of new theoretical approaches. The scientific study of peacekeeping comprises all academic disciplines; in particular, political science, history, sociology, and anthropology have shown great interest in studying its dynamics. The growing bulk of research has led to countless case studies and comparative analysis, several of them addressing the question of success of such operations with respect to the goal of conflict settlement. When Diehl studied six major peacekeeping operations conducted during the Cold War, he concluded with a very pessimistic view stating that they were in the end not very successful (Diehl, 1994). Later studies came to more positive insights, arguing that "peacekeeping after civil wars does indeed make an important contribution to the stability for peace" (Fortna, 2004: 269) and that "it does tend to make peace more likely to last, and to last longer" (Fortna, 2004; Fortna, 2008). Regarding this debate, it is also important to note that, regardless of the conclusions drawn by researchers and scholars, public and elite perceptions about the success or failure of peacekeeping operations often have a significant impact on how much states are willing to engage in such efforts.

Another important factor for conducting comprehensive studies of peacekeeping has been a general desire to learn from previous experiences ('lessons learned') and to improve the performance of ongoing and future missions. As a result, there is a bulk of literature that focuses on the social and political dynamics of peacekeeping and aims at identifying major practical problems and shortfalls of past operations. In this context, a number of 'hot issues' and unintended consequences of peacekeeping are being addressed, including the UN's frequently quoted failure to establish suitable forces for their operations and assigned tasks, and to give them a proper mandate with achievable goals; organizational dilemmas within the UN system leading to critical events (in this respect compare, for example, the respective biographical notes and memoirs of military commanders of UN troops such as Carl Van Horn and Roméo Dallaire); general constraints due to the existing rules of engagement; the potential (psychological and physical) harm to troops and peacekeepers due to stress and the risky character of peacekeeping ('psychology of peacekeeping'); and the involvement of peacekeepers themselves in criminal activities such as human trafficking and forced prostitution.

Within the discipline of military sociology, a number of important societal and social issues of peacekeeping have been investigated thoroughly: recruitment and composition of a peacekeeping force with its practical consequences; behavior and different roles of soldiers in operations; variations in the way units conduct their day-to-day standard military activities; multinationality and complexity and the dynamics of social interaction (Soeters and Manigart, 2008); civil–military relations in peacekeeping operations; perceptions of the operational environment; postdeployment issues; and much more. The theater of operations of peacekeeping, where contingents from many different countries work side by side, has often been the main focus of contemporary sociological studies of

peacekeeping, studying in particular cultural aspects and existing points of tension in such 'complex cultural encounters' (Callaghan and Schönborn, 2004).

Outlook

Today, peacekeeping operations are confronted with a series of new challenges. A general crisis in global economy and increasing economic and financial pressure on Western states make it difficult for the UN, other regional organizations, and single states to commit themselves to new large-scale and long-term peacekeeping operations. This coincides with a general downsizing of standing military forces in many European countries, thus gradually reducing the pool for peacekeeping and shifting the burden even more from Europe to Asia and Africa. Although the UN's role in global conflict management has not radically been called into question in the early 2010s, the debate about a future regionalization of security and of conflict management seems to continue. This discussion is accompanied by a new debate about the proper design and use of peacekeeping forces. Of course, the interplay between great powers and international organizations still has a significant impact on when, where, and how peacekeeping operations are conducted; and this will continue into the future.

Two key questions have always been in the center of all debates about peacekeeping regarding its utility for the prevention and settlement of conflict in contemporary global politics: Which qualities and skills make a 'good peacekeeper'? And what is the best composition of a peacekeeping force in order to guarantee success in the field? The answers given to these questions usually do not differ much; although there has been a trend over time to increasingly stress the importance of the civilian component of peacekeeping and a significant shift with respect to gender, emphasizing much more the enormous importance of women in such endeavors and their specific situations, roles, and needs (see UN Resolution 1325). Frequently, answers have focused primarily on the aspect of 'soldiering' and whether a soldier trained for combat is in fact the right person to be deployed in a peacekeeping operation carrying out completely different tasks than needed for war-fighting. In this respect, former UN Secretary-General Dag Hammarskjöld has often been quoted and is believed to have said that "peacekeeping is not a job for soldiers, but only soldiers can do it." In fact, the military has always been the backbone of peacekeeping operations, frequently counting for more than 80% of all deployed personnel, thus contributing to the creation of new concepts and ideas of a 'soldiering for peace.'

Peace-Making in History

Peter J Lineham, School of Humanities, Massey University, North Shore, Auckland, New Zealand

Abstract

Peacemaking in its contemporary sense is identified within the paradigms of theories of international relations and moral responses to war, and within this definition, examples and precursors are identified and analyzed within the ancient world, medieval and modern history. A particular focus is the growth of peacemaking in the nineteenth and twentieth centuries, first as a system of international pacification and secondly as pacification within civil society.

Introduction

Peacemaking is necessary because of the prevalence of war. It is a new term coined to label and identify activities that work to restore peace in situations of conflict. It is focused primarily on civil war and international conflict, although its methods are closely related to counseling models used to restore harmony within families and local communities.

Peacemaking is carried out by agents, individual and corporate and national, which seek means to lead nations and communities to cease armed conflict. Usually these agents are a third party, which acts as a broker, although sometimes peacemakers may emerge from within one or other of the warring parties. Peacemaking is thus an active strategy to limit war and violence. Processes include mediation, arbitration, and adjudication. Peacemaking may involve the process of seeking resolution to a conflict while the conflict is ongoing, but it may also involve some kind of arbitration of issues after armed conflict has ceased (Ceadel, 2000).

To study a modern concept in a historical context is to analyze changing concepts and practices over the centuries. The historian can identify changes in the practice of war and armed conflict over the centuries and in the same way can trace changes in patterns of reconciliation that led to the modern form of peacemaking.

The changes in warfare have not just been technological but also conceptual. A key aspect of change is the way in which the state has changed its definition over the years. Our definitions of the nation and our idealized concept of the democratic state bear little resemblance to the ancient or medieval state.

Theory Underlying Peacemaking

Notions of peacemaking arise from the application of modern social science theory to debates over the application of moral frameworks to warfare.

Contemporary international relations theories are typically divided into 'liberal' and 'realist' approaches. Realist and idealist theories are both useful in explaining international relations. Peacemaking seeks to adapt the insights of liberal theory so that it can function within the realist tradition. Rational choice theory is the underlying basis of realist theories. Such approaches see war as an inevitable tool used by states in order to strengthen their interests. Realists therefore tend to dismiss Just War theories as mere window dressing. Yet the idea that wars are commenced and ended solely for rational reasons often seems to be contradicted by the practices of 'warmongers.' Some protagonists clearly seek to prolong the struggle in order to inflict maximum damage on their opponents. Longstanding bitterness frequently contributes to the causes and conduct of warfare (Ripson, 2007).

The advocates of the realist analysis sought to curtail the application of morality to the affairs of nations. They analyzed the goals and strategies of armies and states in nonmoral language and focused primarily on the ways in which states furthered their own interests and their success. Yet they were ill-equipped to respond to the deep sense of moral outrage in populations who had lost territory and status through defeat.

The liberal theory of international relations seeks to apply moral language to international warfare, so that wars can be evaluated. Thus it represents a current form of a traditional ethical system, which debated the application of morality to warfare. The Just War theory in its various manifestations sought to constrain and limit warfare.

The theory of peacemaking draws to some extent on *jus in bello* theories that warfare should be just in its conduct and also the *jus ad bellum* that a war should have just causes and likelihood of success. Recent suggestions (notably by Michael Walzer) that war should also be just in the outcome (*jus post bellum*) would also fit with these theories. The criteria of Just War – especially the combination of *jus ad bellum* and *jus in bello* – place so many moral demands on the proponent of war that few wars seem likely to pass the test. Just War theory is thus an incentive to peacemaking. If war is a last and dubious resort, alternatives to war are both moral and practical necessities.

However, since Just War theory is a supposed guide as to when war is appropriate, it is relatively silent on the task of peacemaking. The pacifist traditions have been more aware of the value of working for peace, although only when they have been prepared to risk their traditional absolute opposition to moral compromise.

Peacemaking thus offers a discourse and more important a practice that speaks relevantly to both realists and liberal theorists. Peacemaking moreover brings the two moral responses to war – Just War theory and pacifism – into practical cooperation.

Secular and Religious Approaches to Peacemaking

Religion clearly has been a significant player is some of the most intractable conflicts. Religious wars are always more difficult to settle. Issues of bitterness and grievance can last for

very long periods. So it is appropriate that the practices of peacemaking should come from the same sources.

There has historically been a major issue in getting people to realize that they need to be peacemakers. Peacemaking is often most effectively provided by committed individuals and groups. In the nineteenth century peace societies emerged, which sought to promote missions. In many cases these were organized by Quakers and others who were supporters of peaceful solutions to global problems. William Lloyd Garrison, the antislavery campaigner took this approach in his New England Non-Resistance Society formed in 1838. Tolstoy and Gandhi were influenced by the same trends, sharing a vision of religious harmony, internationalism, and free trade. A peace congress held in 1871 promoted this vision. In World War I internationalist socialists refused to fight as did conscientious objectors to war. In the interwar years further organizations – the Fellowship of Reconciliation and the Peace Pledge Union – also encouraged people to decline to fight. However, none of this effectively made peace; it simply opposed war and almost invariably adopted unilateral actions. This is a typical pacifist approach that did not necessarily make peace.

A strong religious rhetoric is often a feature of moral responses to war. The religious traditions of Buddhism abhorred anger as a motivation in human affairs. Confucianism strongly condemned barbarianism and promoted a healthy secular discourse about the skills of diplomacy.

The practice of peacemaking has also developed strong support from recent moral and religious peace campaigners, many of whom speak of 'just peacemaking' to characterize their work. Distinguished religious leaders including the Dalai Lama, the Pope, and the Archbishop of Canterbury have deployed their own delegates for example Terry Waite. Other scholarly practitioners in various academic centers of peace studies have used psychological and counseling models for their peacemaking and have advocated systems of economic pacification. Mahatma Gandhi and Martin Luther King are example of the impact of high-profile practitioners of peacemaking with their own distinctive strategies. Non-governmental organizations (NGOs) and state agencies have also sought reconciliation between leaders, and former world leaders like President Jimmy Carter have played a significant role.

Part of the problem of peacemaking organizations is that they are based on the liberal rather than the realist tradition in international relations. New strategies have been needed to facilitate peace, shaped within the realist tradition, and this has been the focus of much recent centers of peace.

Religious discussions of war only occasionally acknowledge the influence of realism, but when they have done so their influence has broadened. Reinhold Niebuhr, for example, abandoned pacifism in favor of 'Christian realism,' which argues that the only effective way to limit war is to recognize its prevalence and to find practical ways to control it. Peacemaking fits well within this framework.

Peacemaking in the Ancient World

The ultimate test of the relevance of the concept of peacemaking as a tool of history is whether it applies in the ancient world. The evidence is mixed.

The constant warfare between the Greek states to some extent invited peacemaking, partly because of the role of democratic instruments in choosing to fight or to sue for peace. The Peloponnesian War between Athens and Sparta was a war between a league of states led by Sparta and the modest Athenian empire. Thucydides' account suggests that there were people working for peace in the midst of the struggle. Greek tradition did value peace as well as military virtues. During the ancient Olympics there was some kind of peace that was expected to dominate.

The Romans emerged from the same kind of citizen republic and in the republican period there were examples of peacemaking, but there was also increasing evidence of Roman reluctance to consider any concessions to their enemies. The famous Pyrrhic victory as Asculum in 231 BCE against the Romans seemed to some to be a price too high. The Romans instituted the *Pax Romana*, abolishing war within the empire, and policing its frontiers. They were not uniformly tough on their defeated opponents. Rome had historically effectively shown both a harsh face and a generous face in the aftermath of its victories. Conquered enemies were enslaved, but conquered cities were rarely destroyed. The Romans talked about a punitive peace, a *deballatio*, which generally involved occupation of a state until some kind of penalty or fine was exacted.

The three Punic Wars between Rome and Carthage are a critical turning point in this trend. They made Rome's reputation and brought it to a position of dominance in the Western Mediterranean. In the first two Punic Wars, Rome limited its revenge on Carthage. Then in the Third Punic War, the constant cry of Cato the elder, 'Carthago delenda est,' insisting on the destruction of Carthage urged for a harsh settlement of a territorial threat. At his insistence genocide was pursued, leading to half a million deaths, and many more placed into slavery. Romans pondered the meaning of these events as part of their lessons in statecraft.

Overall, the Roman Empire was a harsh opponent, although Julius Caesar was famous for a generous approach to enemies, and latterly enemies were frequently incorporated as mercenaries into the state.

Theories of peacemaking were guided by the teachings of Aristotle and Cicero and their notion that the moral criteria that justified war should guide the return to peace. The ancient notion of the cycle of history required that there be a return to calm after war. War served as a tool for the righting of wrongs. Cicero in *De Officiis* urged that the end of warfare was a moral victory, where the vanquished acknowledged their moral failure, and then peace was truly attained. Thus Cicero placed a high value upon peace.

Contemporary peacemaking can thus find few precedents in ancient history, except from the Greek age, where democratic states were so frequently at war and in search of peace.

Peacemaking in the Medieval World

In the medieval period, there are many examples that have some similarities with modern peacemaking, although there are also profound differences. One factor that would be unthinkable in the modern approach to peacemaking was the discomfort with religious diversity. Religious diversity certainly

existed in the medieval period but was never regarded as a satisfactory in the long term. This principle explains the crusading tradition that is so antithetical to peacemaking.

Feudal society lacked concentration of power. Authority was dispersed and armed knights were not fully accountable for their actions. Consequently conflicts over lost rights and offended rights were frequent. Many conflicts in the medieval period were the consequence of feudal offences, but this also meant that within a hierarchical society, feudal communities sought arbitrators for warfare.

The key moral authorities were feudal overlords and the church. Their priority lay in reducing the level of violence. The church attempted to curtail violence by regulating the days on which soldiers could resort to warfare under the Peace of God and the Truce of God. The empire and church leaders frequently sought to negotiate peace with honor, sometimes using bribes or other inducements. Church penitentials identified warfare as sinful. The empire believed it was responsible to preserve the Pax. Dependent cities even sent emissaries for peace to their own capital.

The Crusades left a reputation for the brutality of religious and ideological warfare, and they significantly disrupted the Eastern Empire where peacemaking with the new forces of Islam had been remarkably successful. In Western Europe, the Crusades were in part an outlet for the desire for knightly valor, which had been significantly curtailed by attempts to regulate warfare between fellow Christians, which had restricted both the theory of justified war and the days on which knights were permitted to practice it.

As a general rule, medieval theories of the Just War looked to Augustine's theory, in which war was permitted (in contrast to the Christian caution about the vocation of the soldier). Thomas Aquinas spelled this out in his theory in which just cause, right agents, and just goals were all required in a morally justified war. While the concept of peacemaking is not spelt out in this doctrine, the application of Just War doctrine forced kings to consider.

Peacemaking in Modern European History

A significant feature of the nation-state was the placement of formal diplomatic representation in neighboring kingdoms, increasingly on a permanent basis. The first of these were between the small states of Italy at the end of the fifteenth century, but the pattern rapidly spread to the new kingdoms. These diplomatic agents were not usually entrusted with negotiating peace. This required special emissaries in neutral locations.

The interests of the monarch were of central importance in diplomacy and had to be guarded in peacemaking. And consequently status factors were central in war and in peace. Kings were cautious about any hint of independence in the development of foreign offices and the bureaucratization of foreign affairs, although this did occur in the eighteenth century.

While hegemonic forces dominated the European state system, the imperial force was usually endowed with the power of coercion, which could be used aggressively or in the maintenance of peace. Both the Habsburg Empire and the French Bourbon hegemony worked hard to reduce tensions. The advent of a multipolar system in the eighteenth century made the maintenance of peace more precarious. States combined together to block the emergence of a hegemonic power.

This was coupled with the rise of the nation-state and it made the resort to war in the pursuit of national interests much more calculated. The loss of hegemony in the national structure of Europe produced a tradition of alliances and by the eighteenth century a 'balance of power.' Realists saw this balance of power as a way to maintain the peace, whereas others held that a thoroughly developed theory of nations should provide a settlement of grievances.

The rise of Prussia is often cited as a classic example of calculated risk taking in the pursuit of national aggrandisement. In this case, the balance of power and the diplomatic revolution of 1756 were strategies of Austria and France designed to thwart the aggressive stance of Prussia.

General settlements after periods of war offered opportunities for adjustments. The various settlements at the end of the religious wars in 1648, the Peace of Utrecht (1714), the Vienna Treaties at the end of the Napoleonic wars, and the Versailles Settlement at the end of World War I, have each been scrutinized for the their ability to sustain peace.

The processes of peacemaking in the first secular polemical war, the wars of the French Revolution and the wars of Napoleon, are a useful model for the model of peacemaking. There was widespread debate over the nature of the war and the ways to end it, which produced sharply different outlooks from states and from the supporters of the French. The supporters believed in the justice of the cause of the peoples. A party of 'Friends of Peace' emerged among English Whigs in the 1790s who conceived of the issue in geopolitical terms. Immanuel Kant in his book 'Perpetual Peace' (1795) proposed a vision for a peaceful world of nations living in harmony. However, the Napoleonic conflict showed the difficulties of realizing this vision.

The Congress of Vienna and associated treaties were the first to develop models seeking to ensure ongoing peace. Scholars have noted that by addressing broader issues of geopolitics the Congress recognized the deeper dimensions of maintaining the peace. They worked carefully to realign national borders in order to balance state interests and avoid border disputes. Congresses were to be held when necessary to deal with issues threatening war. This vision was a conservative anticipation of twentieth-century internationalism. Countries that had experienced 20 years of war wanted a stable Europe. They were willing to subscribe to a new system of the Balance of Power doctrine, expressed in the Quadruple Alliance. This positively rehabilitated France into European power politics, after a short period of occupation. It also laid down a system of congresses to deal with new issues threatening war, and congresses were held at Aix la Chappelle in 1818, Troppau and Laibach in 1820–21, and at Verona in 1822. However, the heavy-handed conservatism of Prince Clemens Metternich (expressed in the 'Holy Alliance') eventually antagonized the English tradition of constitutionalism and isolationism, and this brought the congresses to an end.

The pattern of consultations between the great powers to deal with international issues survived. The 'concert of powers' frequently consulted to remove potential causes of

warfare. Thus, in the nineteenth century unification nationalism was not wholly a negative force, but the large imperial powers were the critical agencies for peacemaking. The concert accommodated the emergence of various national movements and had a number of signal successes, including the Treaty of London, which guaranteed Belgian independence. The role of Louis Napoleon in brokering peace in Italy to his own political advantage in domestic politics showed an interesting combination of realism and idealism, as he supported the Risorgimento dream of a united national state. Other great power negotiations focused on Schleswig Holstein, the Crimea, Syria, Luxembourg, and Crete. There were other failures, signaled by the Crimean war. It has been argued that after 1848 the resort to war became more common as the conservative tone of Metternich collapsed. It did not succeed in preventing the wars of 1866 and 1870 because when one of the powers determined on warfare, the concert broke down.

The theory of peacemaking at that time was a theory of diplomatic responsibility. Warfare was seen as an instrument of state and politics. Clausewitz, the great military strategist, appreciated the links between war and politics. International relations were based on the assumption that states would act in their national interests and that war was rarely in the national interest. There were also particular factors that affected the peacemaking role of different states. Metternich was preoccupied by the risk of violent revolution. Britain under Palmerston was pressured by a growing democratic system, which idealized moral intervention. Prussia under Bismarck tightly integrated internal and external policy for maximum advantage.

Meanwhile, voluntary organizations committed themselves to a more peaceful international community, some from religious motives and some working from an enlightenment vision of peace and harmony between nations. Peace Societies, sometimes with Quaker links, also contributed. The first was founded in Britain in 1816 and this gradually developed what has been called a pacificist tradition, which stopped short of the pacifists' moral condemnation of all war. A series of national and international congresses gained popular support for ideas to limit warfare. In 1863, the Red Cross movement was founded in Geneva by Henri Dunant and Gustave Moynier after the wars between Austria and Sardinia in Northern Italy. The goal of the organization was the protection and aid for injured soldiers. This was followed at the instigation of the Swiss Government by the first Geneva Convention in 1864, revised in 1906. The Hague Convention was agreed in 1907, which provided laws and customs for land wars. The Permanent Court of Arbitration founded in 1899 was the first permanent international body. The tradition of humanitarianism assisted understanding of the abiding consequences of war and thus laid a foundation for peacemaking. Meanwhile, the Olympic Movement was founded in 1894 with a vision of bringing nations together. The Papacy under Leo XIII having withdrawn from active involvement in Italian affairs gained a reputation as a peace broker. There were also regional peace organizations notably in the Americas as a result of the Hague Conference of 1900. The Nobel Peace Prize was established in 1901 and showed the growing sense of value placed on negotiated peace.

Peacemaking in Non-European History

There are significant different traditions toward the responsibility for peace in the Chinese worldview of itself as the middle kingdom, in the struggles for control of the Indian subcontinent and in African tribal traditions. Some of these diverse approaches became critically important with European colonial expansion. European states intervened in global affairs, disturbing existing structures by exploiting their superior fire power. This asymmetrical relationship made peacemaking difficult, and the only balancing factor at the time was where different European states competed for influence. All such intervention created deep grievances.

Vitoria in his application of Just War theory to the Americas insisted that difference in religion and extension of empire were not acceptable justifications for war. There had to be a wrong committed, and therefore he held that the Spanish could not justify their colonial occupation of South America.

Today post-colonialism has led to a search for indigenous traditions of peacemaking, but so far this has contributed little to the resources of peacemaking.

Twentieth-Century Emergence

It is in the twentieth century that these various factors slowly assembled into a more coherent peacemaking tradition.

After the total warfare of the period 1914–18, the World War I peace negotiations at Versailles reverted to the early ideas of a general settlement. Different ideas of that settlement by the victorious powers left a sense of grievance behind among the defeated German and Austrian powers. The territorial penalties exacted by the French left profound grievances behind. Moreover, the sense of the failure to create a just peace was widespread in the victorious powers. The League of Nations was founded. These factors provided moral grounds for the policy of appeasement, although this was also based on a realistic appraisal of the inadequate preparations for war by the powers. Chamberlain's famous visit to Hitler and the Munich agreement could indeed be regarded as one of the first significant examples of peacemaking.

The Just War tradition profoundly shaped the allied case for fighting World War II. Attempts to negotiate an end to the war were impossible in the light of the absolutist stance of both Germany and the allies. Consequently, the allied war aims called for unconditional surrender of Germany and Japan and justified war trials of German and Italian leaders. Yet the aftermath of World War II did also include attempts to avoid repeating Germany's sense of grievance after World War I, and the Marshall Plan was a remarkably successful attempt to continue peacemaking while the United Nations created the basis of much of the modern discourse on peacekeeping and peacemaking.

The nuclear age and the Cold War restricted the development of peacemaking in the subsequent 40 years. Just War language struggled in the face of the threat of nuclear war. The CND campaigns created a great sensibility nuclear pacifism. East and West in the Cold War developed their positions on realist lines and found on frontiers in Vietnam and other parts of the third world. The ideological rift between the two sides

was profound. Western protestors against the legitimacy of these wars did sponsor some peacemaking missions to Vietnam. Peacemaking thus developed as an attempt to find positive ways to overcome the ideological rift. The United Nations became a crucial setting for negotiations, but some peacemaking avoided this forum.

The formation of the state of Israel and the profound rift with Arab states that resulted was another critical flashpoint during the Cold War and led to a range of great power and local initiatives. Notably in this case the leaders of Egypt and Israel were involved in significant negotiations to settle outstanding issues.

Internationalism

Conflict resolution at an international level has often borrowed the tools of personal and industrial conflict resolution. Such approaches seek each side to understand the point of view of the opponent and analyze both the rational basis of grievances and the feelings that lie behind the others' viewpoint before offering solutions. Some of the means used may indeed be highly relevant, although in foreign affairs this is even more difficult to attain.

The Liberal peacemaking tradition works on the theory that democracies do not easily go to war. Formalized systems and procedures check the advance into war and curtail personal grievances. Yet democracy is sometimes a major obstacle to peacemaking initiatives, as populist voices oppose the righting of grievances. External aggression has proved to be one way to win democratic support.

The conventions of diplomacy have increasingly provided tools to settle issues. Occasionally nations have refused to accept the binding authority of treaties (*pacta sunt servanda*) but these conventions have been highly significant. Some neutral states, notably Switzerland, have been able to play a critical role as intermediaries between other states.

The formation of the League of Nations was very significant as a focus of internationalism. Its goal was collective security and disarmament, and it sought to regulate the conduct of states including regulating against illegal cession of states, but it lacked any military force and was undermined in the 1930s by the withdrawal of belligerent powers. The Locarno Treaties of 1925 sought to normalize relations between Germany and Western Europe. The Permanent Court of International Justice and the International Labor Organization, the Disarmament Commission, the Health Organization, and a number of other bodies were associated with it. The League did play a part in the solution of a number of territorial disputes, but its most ambitious schemes, disarmament and the Kellogg Briand Pact of 1928 and attempts to intervene in disputes between China and Japan, between Italy and Abyssinia and in the Spanish Civil War were massive failures.

The United Nations marked a further step in the evolution of peacemaking structures and rhetoric. Acute awareness of the failures of the League led it to be more closely related to a realistic appraisal of the problems of making and keeping the peace. Its peacemaking and peacekeeping role required the supervision of the Security Council and the agreement of the great powers, each of which was given a veto. This curtailed the powers of the General Assembly, and during the Cold War it rendered most attempts at peacemaking ineffective.

Peace movements particularly focused on the nuclear threat. The Baruch Plan was tabled at the United Nations in 1946, inviting the United States to renounce the use of nuclear weapons so long as no others would develop them. This proved an impossible bargain for those who did not trust the benevolence of the United States. Instead the USSR tested its own atomic weapons in 1949. The Stockholm Peace Appeal of 1950 in fact was one of the steps toward the growth of the Cold War.

Peacemaking work was based on chapter 6 article 33 and chapter 7 of the United Nations Charter. Resolutions have strengthened the powers under this role, but left them condition on the endorsement of the Security Council. Although this has been much criticized, there have been some successes, especially after the end of the Cold War period and the inevitable boycotts of that period. Many studies have shown that the organization is particularly successful over a long period for example in Sierra Leone, where through trial and error solutions are identified and resourced. More immediate flashpoints like Bosnia and Syria and Iraq have proved incapable of great power agreement or the effective neutralization of the issues essential for an internationally agreed solution. The failures of peacemaking can also be linked to the problems in sustaining effective peacekeeping.

The United Nations is however only one aspect of the apparatus of peacemaking. Many other international agencies play an active role. The World Court at the Hague has sought to strengthen peacemaking by treating human rights crimes in wartime as subject to criminal prosecution. War Crimes Tribunals may, however, contribute to the sense of grievance, because of their retroactivity and selectivity. Recent Truth Commissions have included investigations and involving processes of forgiveness as well offer a significant modification of the model.

Other NGOs and think tanks have also sought to foster international understanding and reduce the buildup of hostilities in specific parts of the world, but they all require crucial agreement from sovereign nations at critical points.

Contemporary Peacemaking in Historical Perspective

The argument of this article is that peacemaking is largely a contemporary phenomenon, but it is profoundly affected by the historical legacy of its precursors. There was a rise in civil wars after the end of the Cold War. Also, since the end of the Cold War the problems of peacemaking have been exacerbated by the emergence of terrorism and by the extreme responses of nations to it. The very language of terror makes any action exceedingly difficult.

Contemporary peacemakers have also sought to address internal disruptions and civil disorder to a greater extent than in many of their historical predecessors, and internal and international disputes are more than ever interconnected in an age of terrorism and undeclared warfare. There has been a remarkable institutionalization of peace researchers, supported by government and international contracts and student idealism. The study of peace has also proved highly relevant to the military of many countries.

Peacemaking has a history, but present models of peacemaking are in such distinctive circumstances that historical precedents have limited relevance. However, the realistic development of peacemaking requires that mixed heritage to be taken seriously.

Peace Movements

Marco Giugni, University of Geneva, Geneva Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The origin of peace movements can be traced back to the early nineteenth century, with the foundation of the first peace societies in the Anglo-Saxon world. Issues addressed by the movements include the general fight against war and promotion of peace (including internationalism), antiwar mobilization, nuclear disarmament (including nuclear test ban), mobilization against military infrastructures, and for civil service. Different phases can be discerned in the Western context: the rise of pacifism as a collective and public issue during the nineteenth and early twentieth century; the Cold War era; peace movements as part of the new social movements from the late 1960s to the late 1980s; and the post-Cold War era. The strength and specific features of peace movements vary both across time and across space depending on the specific features of each national context. Today, peace movements are seen as part of the broader family of the new social movements. Scholarly works have characterized the profile of participants in these movements as being rooted in the new middle class, displaying left-libertarian values, and sharing a common concern over social issues, but have also stressed important difference across countries in their social bases. Peace movements find their most important effects at the societal and cultural level rather than at the political level.

Peace movements can be tackled from different angles. Three such angles deserve mention. First, one may look at their underlying ideology and values. Most obviously, this involves fighting war and all the means leading to it (such as weapons or more generally armies) as well as promoting peace in a variety of ways (such as opposing war efforts, sensitizing the public opinion, and educating the younger generations). Second, one may focus on the actors involved. Since social movements are a collective endeavor, this means mainly examining the organizations – both formal and informal – involved in collective efforts to fight war and promote peace. Third, one may stress the actions carried out to fight war and promote peace. Since social movements can be seen as public displays of worthiness, unity, numbers, and commitment (Tilly, 1999), this implies looking at the public expression of the struggle against war and the promotion of peace.

Peace movements, in fact, are all three things at the same time: ideas, people, and actions. In order to get a grasp on their rise and development over time, we then need to consider a broader definition. In this vein, Della Porta and Diani (1999) argue that social movements are informal networks, based on shared beliefs and solidarity, which mobilize about conflictual issues, through the frequent use of various forms of protest. This qualifies peace movements and a special instance of contentious politics, which is a broader analytical category. As stressed among others by Tarrow (1998: 2), "[c]ontentious politics occurs when ordinary people, often in league with more influential citizens, join forces in confrontation with elites, authorities and opponents … When backed by dense social networks and galvanised by culturally resonant, action-oriented symbols, contentious politics leads to sustained interaction with opponents. The result is the social movement." This also distinguishes peace movements from pacifism, which is best confined to the realm of ideas.

From a thematic and substantial point of view, we may distinguish between different branches or, perhaps more accurately, thematic foci of peace movements. The most prominent are probably general fight against war and promotion of peace (including internationalism), antiwar mobilization, nuclear disarmament (including nuclear test ban), mobilization against military infrastructures, and for civil service. To that, we might add the nonviolent movement, which is, however, both narrower and larger than peace movements themselves. The relative strength of each thematic focus varies both across time and across space depending on the specific features of each national context.

From a historical point of view, peace movements have gone through a number of phases, at least in the Western context. Here we address four such phases: (1) the rise of pacifism as a collective and public issue during the nineteenth and early twentieth century; (2) the Cold War era; (3) peace movements as part of the new social movements from the late 1960s to the late 1980s; and (4) the post-Cold War era. Peace movements display specific features in each of these historical phases. The latter are not neatly delimited and sometimes overlap. For example, the peace mobilizations for nuclear disarmament that took place in the late 1970s and early 1980s were at the same time conducted in the context of an exacerbated Cold War climate.

Early Peace Efforts

Peace movements are undoubtedly among the major societal forces that have characterized the twentieth century. Their roots, however, can be traced back to the early nineteenth century. The first attempts to create an organized effort to promote peace emerged in the Anglo-Saxon world, in particular in Britain and the U.S. For example, the New York Peace Society and the Massachusetts Peace Society were founded in 1815, while the London Peace Society was created only 1 year later, in 1816. This early peace reformism, however, has little to do with the peace movements of the mid- and late twentieth century. It is more a matter of movements of ideas led by a small number

of intellectual elites, rather than popular movements involving thousands of middle-class citizens. We can thus talk of pacifism more than peace movements.

Some prominent pacifist associations were founded in the following decades in most Western countries, both nationally, such as for example, the American Peace Society (1928), and internationally, such as for example, the *Ligue internationale et permanente de la paix* (Paris, 1863) and the *Ligue international de la paix et de la liberté* (Geneva, 1867). As their names often suggest, many of these associations worked in the frame of an internationalist approach to peace, that is, based on the assumption that the latter could be reached only through a dialog across national actors and governments. Other transnational associations emerged from wartime pacifism, such as the British and US Quaker service committees (by 1917), the Women's International League for Peace and Freedom (1919), and the International War Resister League (1921). Although many efforts by peace movements have later focused on influencing national governments and public opinions, such an internationalist approach remains alive within the movement until nowadays, and has in fact found new vigor with the rise of the global justice movement in the 2000s.

An important feature of early efforts to fight war and promote peace consists in the strong religious background of peace associations. Often such associations were created that have a strong religious background, in particular of the Christian religion. More generally speaking, often national peace movements divide in two main orientations: a Christian (either Catholic, Protestant, or both) orientation and a leftist (either Socialist, Communist, or both) orientation. The relative strength and importance of each stream depends among other on the cleavage structure in each specific country. Other streams have emerged later on, in particular with the rise of the new social movements in the late 1960s and early 1970s.

Peace Movements under the Cold War

During and in the aftermath of World War II, peace activism and movements continued to flourish within a changed context. This is the context of the Cold War, where the Soviet Union and the U.S. engaged in a tug of war largely based on the nuclear arms race. As a result, peace activism in this period has often focused on nuclear disarmament not only in the U.S., but in Europe as well. At the same time, a peace coalition was formed during World War II around the United Nations ideal, thus continuing the strong internationalist perspective of peace movements. In this context, peace issue and human rights issues were put together in a broader effort to promote peace.

Yet peace activism during this phase mainly focused on the nuclear arms issue. Particularly in the U.S., a number of campaigns were launched which targeted nuclear weapons. This includes the nuclear test ban movements, led by a coalition of organizations that included the Committee for a Sane Nuclear Policy (Katz, 1986). More generally, a grassroots transnational movement formed around opposition to nuclear tests and nuclear arms more generally. This opposition also got the support of leading intellectual figures, such as for example, the British philosopher Bertrand Russell.

A major phase of peace activism occurred during the U.S. intervention in Vietnam and the war that stemmed from it between the mid-1960s and the mid-1970s. Obviously, the American peace movement was at the forefront of this cycle of protest. Indeed, opposition to the Vietnam War represents the peak of the U.S. peace movement, and the Vietnam War also spurred a wealth of protest activities in other countries. In the U.S. the antiwar movement gained momentum starting from February 1965, when American troops began Operation Rolling Thunder in North Vietnam. Opposition started with teach-ins in colleges and then evolved in a wide range of activities involving a broad coalition of congressional critics, liberal intellectuals, radical pacifists, New Left students, as well as disillusioned war veterans. Opposition escalated along with the war, both in terms of the number of events and the number of participants and in terms of the radicalization of the protest. The protest radicalized especially among students within university campuses, leading to what some have qualified of 'campus wars' (Heineman, 1993). At the same time, large mass demonstrations were staged across the country, such as for example, two demonstrations held in Washington: one on 15 November 1969 attended by nearly 500 000 people and another one on 24 November 1969 mobilizing between 200 000 and 500 000 people.

The 'New' Peace Movements

The late 1960s and early 1970s witnessed the emergence of the so-called new social movements. This term refers to a specific type of movements that emerged in Europe after World War II as a product of the shift to a postindustrial society and post-material age, stressing demands that moved away from instrumental issues relating to the class conflict toward post-materialist issues concerning the quality of life broadly speaking (Inglehart, 1977). As such the new social movements are seen as qualitatively different from 'old' movements, most notably the labor movement (Melucci, 1981), in terms of their social basis, ideology, value orientations, and organizational structure, but also in terms of their tactics and action repertoires.

Although some scholars have pointed the environmental movement as being the new social movement par excellence (Touraine, 1978), peace movements are seen as major component of this movement family. In this sense, the advent of the new social movements brought a new impetus to peace movements, bringing a younger generation of activists as well as novel forms of protest. Moreover, the mobilization of the 'new' peace movements reflected the changing structure of social and political cleavage that crossed the European societies in the decades after War World II.

Peace movements have indeed been a protagonist of the wave of protest that has characterized the Western world in the early 1980s. In particular between 1981 and 1983, pacifists across Europe as well as in the U.S. have gathered around the issue of nuclear disarmament, an issue that had been on the agenda of the movements for a long time, but that was took on a new dimension following NATO's decision in December 1979 to base 572 cruise and Pershing II missiles in five West European countries (Belgium, Great Britain, Italy, the

Netherlands, and West Germany). This decision, but above all its adoption by the governments of the countries concerned, led to the mobilization of an antinuclear weapons movement not only in those countries, but also in other countries, including in Eastern Europe. The result was perhaps the largest wave of protest in Western Europe since World War II, with hundreds of thousands of people getting into the streets to protest against NATO's decision and more generally against the nuclear arms race and for peace.

In the U.S., this opposition to nuclear arms took crystalized around the Nuclear Weapons Freeze Campaign. The idea of the freeze as an arms control proposal and a strategy for action was first proposed by peace activist Randall Forsberg in December 1979. It was asked "[t]o improve national and international security, the U.S. and the Soviet Union should stop the nuclear arms race. Specifically, they should adopt a mutual freeze on the testing, production, and deployment of nuclear weapons and of missiles and new aircraft designed primarily to deliver nuclear weapons. This is an essential, verifiable first step toward lessening the risk of nuclear war and reducing the nuclear arsenals" (quoted in Meyer, 1990: 160). The proposal was immediately adopted by pacifists and the movement gained momentum. Protest took several forms: from mass demonstrations and to disruptive actions, to teach-ins at colleges and universities, and to public education tactics. While the Nuclear Weapons Freeze Campaign can be situated between 1979 and 1985 (Chatfield, 1992), 1982 represented the peak of the mobilization. A number of important protest actions took place in that year, including the largest demonstration ever in the U.S. history at that point, when nearly 1 million people filled the street of New York City (12 June).

At the same time, scholars have shown that the mobilization capacity of peace movements – and of all social movements, for that matter – varies very much across countries as a result of different political contexts and opportunity structures (Kriesi et al., 1995; Rochon, 1988). For example, peace mobilization in the 1970s and 1980s was particularly strong in those countries where traditional cleavages such as the class and religious cleavage have been largely pacified, leaving room for the emergence of new cleavages based on postmaterialist issues, and where the configuration of power was favorable for mobilization around these issues. Thus, for example, Germany and the Netherlands witnessed a much stronger wave of protest than France (Kriesi et al., 1995). The ground was particularly fertile for peace mobilization in the Netherlands, as shown by the fact that the largest demonstrations in 1981 and 1983 perhaps took place on Dutch soil, as well as by the huge success of the 'people's petition' of the Dutch peace movement in 1985, which was signed by 3.8 million people (Kriesi, 1989).

Peace Movements in the Post-Cold War Era

The context for the mobilization of peace movements changed dramatically at the end of the 1980s with the fall of the Berlin Wall and the end of the Cold War. This implied a modified frame for pacifism and peace movement mobilization, from a focus on the East–West axis of conflict to an increasing focus on the South–North axis. Also, peace activism shifted away from the nuclear arms issue – with some notable exceptions such as the opposition to France's decision to run a nuclear test series at Mururoa in 1995, which, however, remained quite limited in scope – to a broader range of issues. At the national level, the latter varied depending on the country, addressing military infrastructures, military spending, arms sales, civil service, and so forth. At the international level, the most important events have dealt with opposition to military interventions.

One such events was the U.S. intervention in the Persian Gulf in 1990–91, aimed at driving Iraq out of Kuwait and called Operation Desert Storm, but which became known as Gulf War. This military intervention raised intense opposition from peace activists and more generally citizens. Such an opposition, however, the protest was as short-lived as the war. Quite understandably given the direct involvement of this country, the protest was stronger in the U.S., but peace movements in other countries mobilized as well. Opposition was manifested both before and after the military intervention, but the largest demonstrations as well as the most disruptive protest occurred once intervention began in January 1991. The protest waned as quickly as it rose after cease-fire was called on 28 February 1991.

Another event that spurred an international mobilization by peace movements was the military intervention in the Serb province of Kosovo in 1999 to terminate Serbian oppression in that province of the country made under the banner of the NATO. In part because other armies than the U.S. one were involved in this mission, but in part also because the intervention was done on European soil, this time peace movements in Europe were more active than American pacifists. Perhaps due to the geographical proximity of the country, the protest was particularly strong in Italy.

A few years later another military intervention in the Middle East raised strong opposition from peace movements worldwide. This is the invasion by the U.S. and its allies (Australia, Poland, and the UK) of Iraq between March and May 2003 in what become known as the Iraq War. Among a number of other activities, shortly before the intervention millions of people in more than 600 cities worldwide took the streets to protest against the invasion. In what has been depicted as the largest 1-day protest in human history (Walgrave and Rucht, 2010), pacifists from various countries staged demonstrations on 15 February to cry out loud 'The World Says No to War.' While some of the events were small-scale, others are among the largest demonstrations ever, such as for example, the estimated 3 million people gathered in Rome, Italy. But other large events took place in many other European cities as well as in the U.S.

These three examples illustrate quite well the main focus of peace movements on the global level in the post-Cold War era: protesting against military interventions (mostly by the U.S.) in foreign countries made in the name of freedom and democracy, but which is often seen by pacifists as a neo-imperialist move. Parallel to that, peace movements at the national level have addressed specific issues that may vary from one country to the other. However, these more specific issues only seldom have been addressed publicly, for example, by staging mass demonstrations, and have most often been the object of more 'hidden' advocacy activities by peace movement organizations.

Starting in particular from the late 1990s, peace issues were also addressed as part of a broader agenda of the global justice movement, along concerns around environmental protection, social justice poverty, and inequalities, both nationally and on a global scale. Of course, peace movements have always been strongly internationalized, since the early stages and even more so in the postwar period. However, during the first years of the third millennium peace came to be seen, even more than before, as a global issue and one which needs to be dealt with along other, related issues, most notably human rights and social justice on a planetary scale.

Participants

The literature on social movements can roughly be divided into two main subfields: one dealing with the movements as collective actors, including examining movement organizations (macro and meso levels), and another addressing individual participation (micro level). The same distinction may be applied to the study of peace movements.

Studies focusing specifically on peace activists or more broadly on individual participants in peace movements are rare. Most often, micro level analyses look at participation in social movements in general or, at best, in a given movement family. Scholarly works have stressed the specific profile of participants in the new social movements. Although no consensus exists on this matter, most accounts seem to agree on saying that the ideal-typical new social movement participants are rooted in the new middle class, display left-libertarian values, and share a common concern over social issues (Cotgrove and Duff, 1981; Eder, 1993; Kriesi, 1989). They are thus both structurally and culturally distinguished from 'old' movements such as the labor movement.

This characterization also applies to activists and participants in the 'new' peace movements. However, a number of studies in different countries show a variegated picture of peace movement participants (Parkin, 1968; Kaltefleiter and Pfaltzgraff, 1985; Walgrave and Rucht, 2010). In one of the rare broad comparative analyses of peace movements, the authors have examined a sample of participants in the 15 February 2003 protest against the war on Iraq (Walgrave and Rucht, 2010: 261) with the aim of "analyzing who those demonstrators were, why they took to the streets, and how they were mobilized." The book is based on a comparative protest survey of participants in 11 demonstrations against the (threatened) U.S. intervention in Iraq in eight countries (Belgium, Germany, Italy, the Netherlands, Spain, Switzerland, the UK, and the U.S.).

As the authors stress in the concluding article, "[r]egarding the sociodemographic profiles, of course, the average demonstrator, in the aggregate of all countries, resembled the typical new social movements' activists with high levels of education, a relatively large proportion of whom were women, belonged to the younger age cohorts, and predominantly worked in the human service sector" (Walgrave and Rucht, 2010: 163). At the same time, however, the authors of this research found that there are substantial differences among protesters in the eight countries if the study, attesting to the importance of the context in explaining not only the mobilization of peace movements at the macro and meso levels, but also the characteristics and motivations of individual participants at the micro level. Thus, protesters in the 15 February 2003 demonstrations displayed important cross-national differences in their sociodemographic profile, attitudes, and behaviors.

Outcomes

The study of the outcomes of social movements is at the same time the most neglected and perhaps the most difficult aspect to address, the former probably being a consequence of the latter. Studying the outcomes of peace movements is not an exception to this rule, and students of peace movements have faced the same obstacles as scholars interested in the effects of social movements in general, most notably the problem of establishing a causal nexus between protest and its alleged effects.

Scholars often make a distinction between three main areas of influence of social movements: political, biographical, and cultural outcomes (Giugni, 2008). How do peace movements score on these three counts? Most existing works address political, or even more narrowly, policy effects, founding mixed evidence. For example, while some have found that the U.S. congressional action on the Vietnam War was influenced, at least in part, by antiwar protests (Burstein and Freudenburg, 1978), others show that peace movements have little leverage on policy change (Giugni, 2004a). This certainly holds for the massive mobilizations that occurred in the early 1980s in various European countries as well as in the U.S. and aimed at fighting the nuclear arms race engaged by the two superpowers of the time. In spite of the millions of people involved and their prominence in the mass media, these mobilizations did not prevent the governments of the five countries who agreed with the NATO's decision from actually hosting the nuclear missiles on their soil. Thus, at least in the short term, what was at the time the largest wave of protest in the postwar period was unsuccessful.

Biographical outcomes refer to effects on the life-course of individuals who have participated in movement activities, effects that are at least in part due to involvement in those activities. Scholars have not addresses directly such effects of participation in peace movements, but have looked more generally at the biographical impact of activism in the American New Left during the cycle of protest of the 1960s and 1970s (see Giugni, 2004b for a review). In general, these follow-up studies of New Left activists quite consistently point to a strong and durable impact on the political and personal lives of activists. This suggests that involvement in peace movements, at least if through intense commitment, leaves a strong imprint on the lives of those who take parts in those protest activities.

The effects of peace movements, however, are perhaps most deeply felt at the broader societal and cultural level. Sensitizing national and international public opinions to peace issues, changing cultural orientations with regard to peace and war, affecting the values of the younger generations: this is perhaps where peace movements may have their strongest and most durable effects. That is to say, both pacifism as an ideology and peace movements as the combination of ideas, people, and

actions aimed at fighting war and promoting peace can have their deeper and lasting effects.

Peace Processes

John D Brewer, Institute for the Study of Conflict Transformation and Social Justice, Queen's University Belfast, Belfast, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Peace processes are defined as the series of actions that lead up to the resolution of conflict and the negotiation and signing of a peace accord, as well as the series of actions that implement and consolidate the agreement afterward. A critical distinction is made between political and social peace processes and the series of actions that address these different types are outlined and discussed. The tension that can exist between them is emphasized and reasons are given to explain why peace processes can be so fragile.

To understand what we mean by 'peace process,' we first have to deconstruct what is meant by the word 'process.' The term 'process' normally refers to a series of actions directed toward some end, which need not necessarily be linear but which have some goal as the conclusion. This means that the term 'peace process' describes the often uneven and discontinuous series of actions directed toward the establishment of peace as an end point. We can leave aside here the thorny question of what we mean by peace to concentrate on the series of actions by which it is established and consolidated. Establishment and consolidation are different goals and it is important to distinguish between the actions necessary to establish peace, some of which refer to conflict resolution and peace negotiations, and those which consolidate the conflict transformation to make it more secure after the accord has been signed and implemented. A peace process is thus the series of actions that lead up to the resolution of conflict and the negotiation and signing of a peace accord, as well as the series of actions that implement and consolidate the agreement afterward.

This definition, however, raises another important distinction which will be the main focus here, namely between the political and social peace processes (this was first developed in Brewer, 2010; Brewer et al., 2011). Political peace processes refer to the actions by which peace settlements are negotiated by political representatives and third parties, which involve the negotiation of an accord which brings an end to the violence by which the underlying conflict was pursued, as well as the series of actions established within the compromise agreement by which the terms of the agreement are monitored and the political parties are kept to their obligations under it. It is referred to as the political peace process because these actions involve political management (see Darby and MacGinty, 2000), which includes the establishment of new forms of politically representative institutions, fairer systems of voting, the introduction of human rights law and associated accountability mechanisms, the introduction of a free press, and the creation of procedures by which international observers monitor the accord. Emphasis is placed on a series of actions that introduce structures and institutions of good governance in the view that stable statebuilding is the necessary foundation on which all effective peacebuilding occurs (emphasized most strongly by Call, 2008; see Paris and Sisk, 2009 for some of the differences between the concepts of statebuilding and peacebuilding). In this way, the political peace process constitutes the necessary actions for achieving conflict transformation.

The social peace processes are concerned with the difficult question of societal healing and relationship rebuilding after conflict, and thus refers to the series of actions by which reconciliation in society occurs (on the idea of healing between nations rather than within society see Amstutz, 2004). These actions include truth and reconciliation procedures, forgiveness and atonement strategies, policies that facilitate and encourage public tolerance and compromise, new forms of memory work, memorialization and remembering, public apologies, new cultural symbols, such as national flags, anthems, and the like, and the reassessment and reevaluation of identity. In conflict societies where social inequality is high and was part of the causes of the conflict, as occurs often in settler and divided societies and with wars of decolonization, societal healing is greatly assisted by policies of social redistribution, for people's senses of justice in these types of postconflict society get wrapped up and confused with their experiences of inequality; the demand for justice is a surrogate for demands for social redistribution. When this confusion occurs, the social peace process is affected by the forms of economic policy adopted in the postconflict phase (see Boyce and O'Donnell, 2007) and must concern itself with social policies that address inequality as much as injustice. In all these ways, the social peace process involves a process of social transformation that is much wider than the process of conflict transformation and deals with issues that are deeply emotional and well beyond the usual terrain of the political peace process.

The series of actions through which societal reconciliation is addressed can occur in the preagreement phase as part of the political peace process, as attempts at relationship rebuilding are encouraged in the lead-in to the negotiations or the possibilities of compromise are explored as part of the political debate to enhance the success of the negotiations. Mostly, however, the social peace process builds on the political peace process as conflict transformation opens up spaces for exploring the possibilities of restoration and rebuilding once the violence has stopped or downscaled. The social peace process can be a precursor to the political peace process therefore, but tends to proceed apace only once the political peace process is underway.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96043-4

The distinction between these two forms of peace process is important for understanding the tension that often occurs between them in the postconflict phase. It is often assumed that a peace process is successfully accomplished and comes to an end when conflict transformation results in a negotiated political settlement that introduces good governance structures and stable statebuilding. Fairer systems of voting, more representative forms of political institutions, legal systems that enshrine human rights law or bills of rights, a free press independent of regime interference and workable institutions for decision-making and policy implementation are among the main features of statebuilding as the route to successful peacebuilding. These actions form the main concerns of the political peace process. However, it is naive to assume that social healing and reconciliation automatically follow once problematic politics are negotiated away and good governance structures are implemented.

For one thing, political peace processes are mostly fragile (see Brewer, 2010, pp. 29–43), since accords go through various iterations and parties to the agreement often abrogate their responsibilities under it. There are many reasons for this. Some of these are obviously political. Weak governments often result in the new institutions becoming unworkable. Peace accords reflect the decision of all parties to opt for a second-best preference (the compromise arrangement) and to give up their first-choice option (victory) for the sake of peace. However, dissidents who oppose the settlement can continue with a campaign of violence to undermine the new institutions, escalate the costs to the economy of the peace process, and force the continuance of militarization in a way that inhibits both statebuilding and societal healing. This 'spoiler violence' (a term used in Stedman, 1997) destabilizes the political and social peace processes, such that ongoing violence is dangerous to the consolidation of peace and can perhaps call into question to capacity of the new governance structures to deliver or respect human rights, fairness, and justice (on the general negative effects of violence on peace processes see Darby, 2001). It is for this very reason that those who wish to see the continuance of conflict, make military targets of those moderates who are prepared to cut a deal, often reserving the worst barbarism for their erstwhile colleagues, and why levels of violence can actually increase during the interregnum when a peace accord is being negotiated (in South Africa's case see Du Toit, 2001), although the latter can also happen as a deliberate ploy to increase militants' bargaining power at the negotiating table.

Some reasons for the fragility of the political peace processes are also economic. Spoiler violence can be motivated by the wish to continue to benefit materially from a war economy, and war economies are often made all the weaker by the costs of militarization involved in pursuing dissidents and spoilers (on war economies see Collier, 1999; Keen, 1998). The descending cycle of failed economy, failed government, and failed statebuilding puts political peace processes to a severe test. War economies permit corruption to go relatively unchecked, often involving the fraudulent exploitation of foreign aid, as well as encouraging a system of patronage that facilitates rich war lords to retain large armies for personal as well as political and economic gain. The ending of war economies can be hugely problematic to the patrons as much as the war lords, especially where the economy is weak and does not offer economic opportunities that improve much on the level of patronage, giving them all a material interest in the continuance of violence. Where the patrons are children, in the form of either child soldiers or young girls used for sexual exploitation by adult male soldiers, the use of which has dramatically increased as forms of organized violence have intensified in late modernity (see Honwana, 2006), their economic reintegration is all the harder, especially where their education was interrupted by the conflict. War economies weaken states and make them open to further destabilization from dissidents, resulting in failed political deals in an endless cycle of violence.

Political peace processes can be fragile also for psychological reasons. This can be misunderstood in the mistaken view that the end goal of peace has to be universally desirable. Yet violence can be all that some people have known and peace comes with its own ontological costs. Peace processes require people to reevaluate themselves in relation to their former enemies. People are required to reassess who they are and who is their enemy, perhaps having to overcome centuries of cultural socialization and stereotyping of 'the other,' to now see their erstwhile enemies in government, and to question their own identities and former privileges. Peace can sometimes come at too high a price for some people, with the ontological insecurities of continued violence posing less of a challenge to their identity than peace itself. It is for this reason that, counterintuitively, some people can look back on political transitions through glasses darkly, seeing in the past greater security, stability, and safety than in newly democratic times. These people form a residual constituency of support for deposed antidemocratic regimes and parties not for political reasons but because they experience political change as increasing their ontological insecurity. It constitutes a form of transition stress that encourages romanticized views of the security found in failed regimes in the past.

However, another of the recurring weaknesses in political peace processes is that they leave unresolved the difficult question of societal healing and relationship rebuilding, or assume that this occurs naturally once problematic politics are resolved. The processes for social transformation are often neglected in the political peace process as parties to the negotiation concentrate on bringing warring factions to the table, keeping them there, and eking out the basis of an agreement through trying to establish workable governance structures and institutions. Peace accords therefore rarely discuss the measures by which postviolence societal healing is to be effected. Peace agreements, for example, rarely specify in detail how truth recovery is to be conducted, what policies are to be implemented to aid victims or socially reintegrate former prisoners, or how postconflict social redistribution should be addressed. But it could be argued that the social peace process only really begins once conflict transformation has begun and that peacebuilding requires as much attention to the issue of social reconciliation as it does to statebuilding. Paris and Sisk (2009), for example, have recently analyzed some of the contradictions between statebuilding and peacebuilding and highlight that effective statebuilding presupposes progress on issues within the social peace process like dealing with the past (for the contradictions between statebuilding and peacebuilding in Afghanistan see Rubin, 2006).

The social peace process requires policy makers to focus on a broader set of issues than is normally captured in our understanding of political peace processes. Some of these concerns are dealt with under the notion of transitional justice (on transitional justice in postconflict societies see Braithwaite, 2002; Brewer and Hayes, 2011; Elster, 2004), which is now understood to mean more than the criminal processing of conflict-related crime in either retributive criminal courts or restorative justice procedures. Transitional justice these days covers the whole process of social reconciliation and societal healing after conflict. Issues around amnesty for excombatants or early release of prisoners are particularly difficult to resolve given the preference many victims have for retributive justice through the criminal courts (for elaboration see Mallinder and McEvoy, 2011), but restorative justice procedures have been deployed in many cases where traditional notions of authority survived the conflict and where they already contained strong restorative elements, notably the famous *gacaca* courts in Rwanda (on which see Cobban, 2006). Where these traditional systems of authority have not survived, advocates of restorative justice policies had tended to prioritize truth recovery as the nearest form of restoration between victim and perpetrator (for example, Braithwaite, 2002). It is rare for truth commissions *not* to be part of postconflict recovery ever since they were popularized in Latin America (for a review see Hayner, 2002) and made universal as a result of the high-profile activities of the South African Truth and Reconciliation Commission (on which see Rotberg and Thompson, 2000; Shore, 2009; Wilson, 2001). They have become almost the panacea for societal reconciliation.

However, the social peace process is much broader than truth recovery. It involves policies for managing victimhood, assisting in the social reintegration of former combatants and child soldiers, citizenship education courses to address the past, new forms of memory work and memorialization, the various atonement strategies that deal with public apologies and forgiveness, policies of economic restructuring and equality of opportunity, and new identity formation processes and practices in art and performance (for a review of the role of art in peacebuilding see Shank and Schirch, 2008), literature and writing, peace journalism (for an introduction to this field see Lynch and McGoldrick, 2005), sport (sport and peace is a growing interest; see Giulianotti, 2011; Hoglund and Sandberg, 2008; Sugden, 2008), museums (on museums and peacebuilding see Crooke, 2005; Shearing and Kempa, 2004), gender mainstreaming (for a summary of the huge literature on gender and peacebuilding see Brewer, 2010, pp. 68–102), the school curriculum, among other things.

All of these things rightly come under the rubric now of 'peace process,' making it an interdisciplinary interest that extends beyond political science, international relations, and human rights law, the traditional disciplines that focused on statebuilding in the political peace process. Peace processes are now as much the domain of psychology, economics, memory studies, sociology, sports studies, drama and the performing arts, cultural studies, and theology and religious studies. Theologians, for example, write as much on political forgiveness as hard-nosed political scientists (for reflections on political forgiveness within theology and politics see Digeser, 2001; Griswold, 2007; Jankélévitch, 2005; Shriver, 1995; Torrance, 2006), psychologists on victim issues as well as medics (see Hamber, 2009), sociologists on atonement strategies as much as human rights lawyers (see Brewer, 2006; Misztal, 2003, 2011a).

Interdisciplinarity is not the only advantage that follows from this new way of approaching the conceptual field in peace processes. There are practical policy benefits. When the emphasis was placed entirely on the political peace process, the domain for its operation and implementation was correspondingly political. Peace processes were the responsibility of governments, and the political actors that made up or aspired to be governments, as well as the political parties who once formerly opposed them militarily. Political actors negotiated the settlements, they occupied the new governance structures and oversaw the new institutions, and they either endorsed or collapsed them, making political decisions about whether to abrogate or stick with it. International political actors often assisted in this responsibility, in the form of third party governments or international actors connected to regional power blocs or the United Nations. In this view, peace processes were political affairs, commanded over by politicians, the future of which was the responsibility of political actors.

Once we give recognition to the idea of the social peace process, peace processes become everyone's responsibility and the domain in which they function and are consolidated widens to include civil society (for an analysis of the role of civil society in peace processes see Brewer, 2010; Brewer et al., 2011; Kaldor, 2003; Van Leeuwen, 2009). It has become fashionable to emphasize the importance of civil society in peace processes, with several philanthropic foundations funding initiatives that promote the growth of civil society in postconflict societies (see Anheier and Daly, 2005). This recognition, however, is not just a consequence of the huge number of civil society groups that are involved in peacebuilding or the sizable funds now available to fund them, for civil society is a crucial domain in which the social peace process is enacted. While only a minority of peace agreements make explicit reference to civil society (see Bell and O'Rourke, 2007), as befits the orthodoxy that peace processes are essentially political, civil society has come to be seen as critical in several respects when dealing with the aftermath of conflict.

This usefulness includes the role of civil society groups in the allocation and distribution of resources and humanitarian aid, the monitoring of parties' obligations under peace accords, the provision of participative forums to widen civic engagement and deliberation, and direct involvement in societal reconciliation. In this regard social peace processes benefit from the involvement of, for example, faith-based organizations in dealing with issues that fall within their compass and competence, like public engagement with the meaning of forgiveness, hope, and healing (on the phenomenon of religious peacebuilding see Brewer et al., 2011; Coward and Smith, 2004; Herbert, 2003; Shore, 2009; Schlack, 2009), or women's groups with respect to encouraging gender empowerment, trade unions with pressing questions of inequality, or peasant groups with land redistribution, universities, schools, and youth groups in pushing for educational and curriculum reform and wider access to

education, medical aid agencies with respect to victims and trauma or in managing the medical problems left from gendered violence, or human rights groups with respect to continued abuses or in advancing the application of international norms of justice in whatever localized restorative justice procedure is adopted, and so on.

This fundamentally shifts responsibility for social peace processes to make them practitioner based not just politician led. Religious actors are not politicians, peasant leaders mostly do not want to build constitutions, or members of women's groups rule the country. Yet within spheres of competence, members of civil society groups can become effective peace agents as practitioners within the grassroots. Recognition of peacemaking as a practitioner activity has spurred the growth of civil society in postconflict societies as well as given impetus to the emergence of an industry in training manuals, training workshops, peace studies courses and summer schemes, and direct public engagement through forms of civic or peace education (the practitioner nature of civil society is emphasized in Van Leeuwen, 2009). This industry is not to be undermined, for some of the main weaknesses postconflict societies face lie with the feelings of disempowerment in the grassroots arising from the view that the peace process is the politicians' responsibility not theirs, as well as the tendency of civil society groups to reproduce the preagreement divisions and cleavages as they split along traditional lines (in Sri Lanka's case see Orjuela, 2008; on problems with the 'darker side' of civil society see Chambers and Kopstein, 2001). This means that civil society groups play a significant role in trying to persuade people to feel they can make a difference in the social peace process. In so doing they should not themselves reproduce the old lines of division but work together to deal with the pressing issues that define the problem of social reconciliation.

It is important, however, not to set up the political and social peace processes as mutually exclusive and competing series of actions. They have, after all, the same end goal, the conclusion of peace, and its consolidation. The relationship between them is also recursive. Progress in the social peace process prior to a political settlement, in the form of cross community and civil society initiatives that challenge the terms of the conflict and bring enemies together, can assist the negotiation of a peace accord, facilitating the success of the political peace process. On the other hand, the consolidation of the settlement and the bedding down of the new governance structures and institutions is greatly assisted if the problem of societal healing is broached and systematic attempts are made to facilitate social reconciliation. In other words, the social and political peace processes complement each other and problems arise in postconflict societies only if the policy emphasis and reconstruction and aid money neglects one in favor of the other.

They do, nonetheless, operate on different time frames. Governance structures and institutions can be quickly devised and implemented. Statebuilding in the political peace process can advance quickly, if not necessarily always successfully. Foreign aid money can bolster weak economies rapidly, so long as it is sustained, and new systems of voting can result quickly in fairer elections. This compressed time frame is partly the reason why peace processes can be wrongly perceived to have reached their conclusion when the new institutions are up and running. There is, of course, acceptance that new governance structures take time to institutionalize and become embedded but this is seen as just a matter of time. Institutions carry their own institutionalization in time. Social reconciliation, however, has to operate on a much longer time frame. This is sometimes a source of great frustration as outsiders – as well as some insiders – in the global publics as well as international politicians get exasperated when ancient conflicts erupt at flash points or when people in societies emerging from conflict seem not to have learned the lessons of the past. The social peace process, however, is of long duration. Some changes to cultural and national symbols can be quickly implemented – changes to flags and national anthems need little time (on the problem of managing culture in postconflict societies see McEvoy, 2011) – but shifts in culture, identity, socialization patterns, gender relations, and the rest take generations. This is one of the reasons why institutional reform in the political peace process can be seen to be progressing well while interpersonal antagonisms and group conflicts continue, and societal reconciliation seems as far away as ever.

Two things follow from these temporal considerations. Social peace processes require patience. They also demand sustained attention. If trust is a casualty of war, patience is of peace. Time frames of expectation are very short as people want peace on their terms and want it now. But forgiveness, truth, reintegration, and healing are for the long term, and patience is required because reconciliation proceeds slowly, stumblingly, and sometimes falters. The contradiction is clear. On the one hand, the social peace process poses people challenges that make it difficult to embrace former enemies, while conversely, people get frustrated and exasperated when old resentments and divisions resurface. This is the paradox of social peace processes. They have within them an inherent contradiction provoked entirely by the problem of expectations. There are two dimensions to the problem of expectations. Most people want societal healing but without themselves having to change. 'The other' has to make the compromises; it is 'them' not 'us' who have to reform. Most people expect accommodation in others, not themselves; they do not consider they have to move an inch. The second dimension to the problem of expectations is that most people want the benefits of peace to accrue to themselves and their group not to 'the other.' They do not want to see former enemies benefitting; if it seems that they are being rewarded, their commitment to the social peace process weakens in the view that it is one sided. For these reasons, the problem of expectations can stymie the social peace process, and the flash point outbreaks of renewed conflict the problem of expectations provoke can infect the political peace process and cause strain in the working of the new governance structures.

The problem of expectations can be resolved, however, by recognizing the importance of patience – patience toward others when they seem uncompromising and in ourselves when we feel the same. And the time frame for meeting expectations can be compressed if the social peace process is given the serious attention it deserves by practitioners in civil society and politicians and policy makers in the new

governance structures. Discharging this responsibility is critical, getting recognition of it as an obligation even more so. This means faith-based organizations have to become actively involved in managing the tensions within the social peace process as patience and compromise breaks down, so too women's groups, trade unions and peasant groups, businesses, universities, schools and youth groups, victim support groups, and the rest: it is not just the responsibility of politicians. In short, empowering civil society as practitioner peacebuilders accelerates the social peace process.

There is one further advantage to the new conceptual field by which we understand the nature and development of peace processes. Peace processes are not solely political processes anymore but moral ones (see Lederach, 2005 for the strongest statement of this). This has significant implications for how we conceptualize them. To understand this, it is first necessary to appreciate the changing nature of war and organized violence in late modernity (on which see Malesevic, 2010). Organized violence has escalated in this period and transformed into what Kaldor calls 'new wars' (1999), dominated by intrastate conflict, without a set battle zone and involving large numbers of noncombatants: violence of a kind that no longer involves professional armies but engages the whole of society, whose resolution equally prompts a broad response that involves civil society (a point emphasized by Van Leeuwen, 2009, p. 38). This new form of organized violence also involves the human body being turned into a battle site as barbaric atrocities come to be inflicted on enemies, sometimes with premodern forms of weaponry like the machete, often with sophisticated weaponry that is now more easily accessible, like land mines (as this affects women's bodies in particular see Hynes, 2004). Turning the body into a battleground reflects the moral enervation of the enemy, in which they are stripped of moral worth and dignity and not recognized as human or deserving respect as humans. This is most obviously the case in instances of genocide (on which see Shaw, 2007), which is designed to destroy a whole people, but is also the case in other forms of organized violence (see Halpern and Weinstein, 2004). Paradoxically, this expansion in the barbarity of organized violence is matched simultaneously with the increased regulation of the conduct of war, with the growth in institutional norms that monitor war crimes, the introduction of United Nations' regulatory mechanisms of accountability and enhanced international intervention in local and regional wars, all justified on moral grounds to protect the human rights of innocent civilians. This has increased the tendency of the international community to intervene in local wars not only for reasons of *realpolitik* but now also for humanitarian purposes. Reconciliation is seen as a moral imperative (see Walker, 2006).

The combination of these two processes – greater levels of organized violence and its increased international regulation – has made peace processes and postconflict reconciliation burgeoning intellectual interests for a wide range of practitioners and academic disciplines because peace is recognized as raising deeply moral questions that touch on the nature of the normative values that define late modern ideas of humanitarianism (or what is increasingly called cosmopolitanism, on which see Beck, 2012; Delanty, 2009). There is a profound cultural shift occurring globally into which this moral interest in peace processes has to be embedded. Many sociologists advance the claim that feelings of responsibility toward strangers and their 'distant suffering' are beginning to mark the human condition (see Boltanski, 1999). Globalization has compressed time and space in a way that brings distant others into the daily experience of late modern life. Television brings distant suffering into people's living rooms and new forms of social networking technology like Twitter and YouTube collapse time and space, giving distant suffering immediacy to the point where images of distant suffering bombard late modernity. Global digital media give visual form to the material conditions of political economy that cause the distant suffering and which provoke a humanitarian response (see Sayer, 2000 for the link between the moral economy of late modernity and its political economy). This is in part due to an emerging sense of the shared vulnerability of humankind. Sociology is beginning to pick up on this shift, affecting sociological treatments of human rights (Turner, 2006), the emergence of what Wilkinson calls the sociology of suffering (2005), Mizstal's (2011b) attempt to chart the sociology of vulnerability, in Delanty's outline of late modernity's 'cosmopolitan imagination' (2009) and in notions of justice that prioritize human dignity over socioeconomic redistribution (for example, Wolterstorff, 2010).

This moral sensibility, of course, should not be exaggerated. Antiforeigner sentiments and aggressive xenophobia are equally evident and exist alongside ethical cosmopolitanism. As the German sociologist Ulrich Beck (2012) argues however, the world is in a process of cosmopolitanization, of arriving toward rather than yet having achieved cosmopolitanism. Cross-national comparative research by Pichler (2012) on cosmopolitanism at the interpersonal level (rather than the usual macro-level attention to cosmopolitanism) shows it to be uneven across its various dimensions (also see Norris and Inglehart, 2009), such as in politics (global governance), identity (notions of global citizenship), and ethics (empathy and trust toward others). Using World Value Survey data from 49 countries between 2005 and 2008, Pichler (2012, pp. 28–31) shows ethical cosmopolitanism to be more prevalent than political cosmopolitanism, especially in the global first world and among urban dwellers, the highly educated, and professionals. A cultural shift is thus unevenly occurring, but in significant sections of the population in many late modern societies, moral sensibility is motivating an interest in peace processes. It is for this reason that moral philosophers (for example, Margalit, 2009), theologians (for example, Brudholm, 2008; Brudholm and Cushman, 2009), cultural sociologists (for example, Alexander, 2012), and the like concern themselves with the nature of societal healing after trauma. Moral reflections like these on the boundaries and limitations of memory (for example, see Ricoeur, 2004; Volf, 2006), forgiveness (for example, Brudholm, 2008), and truth (for example, Braithwaite, 2011; Rotberg and Thompson, 2000) are turning the study of peace processes into a modern form of an ancient concern with the nature of moral sensibility.

Abstract

Psychological processes such as enemy images, ideology, and obedience to authority mix with political, economic, and social factors to fuel destructive conflict. Following armed conflict, psychological processes can help to heal the emotional wounds, promote nonviolent conflict resolution, and improve intergroup relations. Psychologists promote social justice and prevent violence through work on transitional justice, policy advocacy, and peace education.

Introduction

As far back as William James, who argued in 1906 that societies need to develop morally appropriate yet exciting alternatives to war, psychologists have been active in promoting peace, defined broadly to include both negative and positive peace. Negative peace includes efforts to reduce or contain violence, whereas positive peace includes efforts to reduce social injustice and the structural violence caused by inequalities and denial of human rights (Christie et al., 2008). Attention to structural violence and positive peace is often achieved through work not only on militarism but also racism, sexism, classism, and corporate greed. Taking a multidisciplinary perspective, this article examines the psychological origins of war and destructive intergroup conflict, psychological approaches to postconflict peacebuilding, and psychologically informed work on building social justice.

Causes of War and Destructive Intergroup Conflict

Armed conflicts, including the intrasocietal conflicts that are now the dominant form of war, have complex political, historic, economic, religious, and cultural roots. Much destructive conflict owes to a divergence of objective interests such as competition over scarce resources such as land, oil, diamonds, and water, and worsening life conditions. The multidecade series of armed conflicts in Afghanistan, for example, have been in part struggles over land and contested political power, including the power sought by the Taliban to impose an extremist form of Islam on the country. Contestation over objective interests has also animated conflicts in Iraq, Palestine, Sudan, Colombia, Democratic Republic of Congo, Sudan, Sri Lanka, and Rwanda, among others.

Enemy Images and Cognitive Biases

In addition to these objective sources of armed conflict, there are a host of subjective, psychological sources that interact with the objective sources and that need to be analyzed and addressed in building peace. For example, as conflict over resources escalates, negative psychological dynamics stimulate spirals of hostile perception and behavior, and become self-perpetuating parts of the conflict process. The parties to a conflict often experience mutual fears, which may include the existential fear that the other group seeks to annihilate or exterminate one's own group. Accompanying and inflaming these fears are enemy images, which are demonic stereotypes of the Other that develop alongside of a heightened sense of the 'Good Us' (White, 1984). The dehumanized nature of these images, which may be expressed in popular media, political rhetoric (e.g., the 'axis of evil'), and political cartoons encourages moral exclusion, the psychological placement of the enemy outside the moral universe.

These images may also bias perceptions by leading adversaries to make negative attributions or inferences about the Other's behavior or motives. For example, a group that already fears an impending attack may view troop movement by the adversary as offensively motivated when in fact the adversary had moved the troops for defensive purposes. Harboring such images and fears and having biased perceptions, adversaries may view violence as both justified and necessary. Indeed, political leaders frequently manipulate these images to stir up war fever and prepare the public for genocide and other mass violations of human rights such as the use of torture against terrorists and the creation of black sites that operate outside the dictates of international law.

Subjective influences are visible also in the biased decision-making of policy elites. Many leaders' aversion to losses encourages excessive risk-taking and departure from rational decision making. In intense conflicts, leaders may experience powerful fears, which motivate misperceptions regarding their adversaries' motives, strength, and willingness to fight. As international tensions escalate, leaders may experience a cognitive constriction evidenced in reduced complexity of views of the adversary expressed in speeches. Leaders may also use inappropriate historical analogies to guide thinking about current crises. Under pressure of crises, small leadership groups having a strong *espirit de corps* and a charismatic leader may make flawed decisions guided by premature consensus, a sense of invulnerability, failure to weigh moral concerns, internal suppression of dissent, and poor contingency planning (Janis, 1982).

In a variety of contexts, obedience to authority is a powerful enabler of armed conflict and of mass violations of human rights. Obedience is particularly strong when the person giving the order to fight is seen as the legitimate leader of the country and as facing a diabolical enemy who cannot be dealt with through peaceful means. Obedience, however, seldom acts alone but combines with diverse factors such as progressive

 http://dx.doi.org/10.1016/B978-0-08-097086-8.22013-8

exposure to violence, the failure to meet basic needs, the lack of bystanders who intervene to prevent violations, and ideologies of good and evil, among others (Staub, 2011).

Social Identity, Societal Narratives, and Ideology

Armed conflict also has subjective sources such as social identity, societal narratives, and ideology. Even when no objective divergence of interest exists, people tend to categorize themselves as belonging to different groups and to show in-group favoritism in judging people, thereby attaining self-esteem and positive self-identity from identification with the in-group (Tajfel, 1982). Typically, they judge others relative to the standards set by the in-group, leading to ethnocentric attitudes. In normal circumstances, such attitudes may lead to provincial thinking but not to violence.

Although identity differences do not themselves cause violence, they may become part of a system of violence in settings of intense fear, mistrust, and real or perceived wrongdoings by the other group. As seen in the Northern Ireland conflict, people who have been attacked by another group may see their identity group – Catholics or Protestants, respectively – as under assault and may experience existential fear as a result. As members of a group are attacked, members of the group create narratives and communal memories about the trauma and damage that the other group has inflicted on them. They form 'chosen traumas' (Volkan, 1997) that they integrate into their social identity and transmit to their families and communities through a mixture of stories, memorials, and other means. Over time, the attitudes and perceptions of each group harden, and identity issues become central to the conflict. These dynamics have been visible in pregenocide Rwanda and also in intractable conflicts such as the Israeli-Palestinain conflict and the Cyprus conflict.

Views of the out-group as threatening and implacably hostile may become sufficiently widespread that they form a social ethos (Bar-Tal, 2007) or informal ideology. Such ideologies are self-sustaining sources of the conflict and are highly resistant to change. The power of ideology, however, becomes most apparent when it is constructed and legitimated by a State, which uses its control over the media and ability to stir the fires or nationalism and whip up public hysteria to instigate mass violence, including genocide. For example, before the Rwandan genocide, President Habyarimana, a Hutu, used mass media to create an ideology of hatred toward Tutsis. Similarly, Hitler used an ideology of racial superiority and global Jewish conspiracy to fuel antisemitism and enable the Holocaust. As these and other examples suggest, key tasks of the psychology of promoting peace are to discourage such ideologies of hatred, racial superiority and violence, and nurture instead peaceful social identities and ideologies of nonviolence.

Postconflict Healing and Peacebuilding

In the aftermath of war, two key psychological tasks are to heal the psychosocial wounds of war and to support peacebuilding processes such as nonviolent conflict resolution and transforming systems of structural violence and oppression. Conceptually, there is a reciprocal relation between psychosocial support and peacebuilding. A significant impediment to peace following armed conflict is the ongoing fear, trauma, and distress that people experience and weave into their social identities. Healing the trauma and distress of war makes it easier to build positive relations between previously hostile groups and to build social and political unity. Conversely, the improvement of relations between groups helps to reduce the intense fear and hostility that stress people and impede healing. For ease of exposition, these are discussed separately below.

Mental Health and Psychosocial Support

Armed conflict has diverse and potentially profound effects on people's mental health and their psychosocial well-being. Mass exposure to attack, violence, and death typically increases above their baseline rate the levels of mental disorders such as depression, anxiety, and posttraumatic stress disorder (PTSD). PTSD, which frequently receives extensive attention following armed conflict, is characterized by reexperiencing horrible events, emotional numbing, and hypervigilance. However, it cannot be assumed that PTSD is the most significant psychological issue or that everyone has it. Consensus practice guidelines indicate that the effects should be identified through a systematic assessment of diverse clinical issues and the use of contextually appropriate measures (IASC, 2007).

In addition, many psychological effects of war are not individual but relate to the damage of relationships and to social divisions and destruction. These interacting psychological and psychosocial effects – referred to collectively as the mental health and psychosocial effects of war – may not reach clinical intensity yet cause significant suffering and distress. Prominent among the psychosocial effects of war are loss of loved ones, family separation, destruction of one's home and community, inability to meet the basic needs of one's family, unemployment and lack of a livelihood, and fear of further violence. A significant source of distress is the sexual violence that occurs frequently not only during war but in communities and in refugee and displacement settings following armed conflict.

The psychosocial effects of armed conflict vary by gender, age, and culture. For example, the threat of sexual violence is often higher for girls than for boys. Similarly, the lack of education and employment may be a larger problem for teenagers than for children who are 7–12 years of age. People's culturally and socially constructed beliefs and practices also influence the psychosocial effects of armed conflict (Wessells, 2006). For example, young people who had been recruited into armed forces or groups and who had killed people may believe they are haunted by the angry spirits of the people they had killed. They and their family and community members may see this as a collective affliction if the local beliefs are that angry spirits wield enormous power and can cause crop failure, deaths, and even war. Such culturally situated beliefs are not static but continually undergo change as new ideas and practices enter the social system. Like mental health effects, the psychosocial effects of armed conflict vary according to the context and should be identified through systematic assessment (IASC, 2007).

The field of mental health and psychosocial support in humanitarian crises has a weak base of evidence regarding which interventions are most effective and sustainable. Evidence from diverse settings suggests that key steps are to support survivors' sense of self-esteem and self-efficacy, particularly in a context of building positive social relations and community mobilization. Also of high importance are cultural supports such as the conduct of burial rites for the dead and the conduct of spiritual cleansing rituals to appease or reduce the influence of the angry spirits discussed above.

Practitioner expertise indicates the need for multiple levels and kinds of mental health and psychosocial support, which include a mixture of naturally occurring supports and those organized by psychologists, governments, or humanitarian agencies. These levels can be envisioned as an intervention pyramid. The base of the pyramid, which applies to the greatest number of people, consists of meeting basic needs such as those for food, shelter, water and sanitation, and health care. When these needs have been met, people benefit from natural supports such as those provided by family, friends, and social interaction with peers, women's groups, youth groups, and religious groups, among others. The second level – family and community supports – includes steps to reunite children separated from their parents and to reestablish normal processes such as education, which is a significant source of psychosocial support for war-affected children. The third level consists of focused interventions for people such as survivors of rape and gender-based violence who may face specific issues such as stigma and need legal and health support. The top level, which affects a smaller number of people yet is of considerable importance, consists of specialized interventions such as therapeutic counseling for the most severely affected people, who may be overwhelmed or unable to function in everyday tasks such as working or, for children, going to school. In war zones, all four of these levels of support are needed, yet it has proven difficult in practice to establish and coordinate them or to develop the referral mechanisms needed in such a systemic approach.

Postconflict Peacebuilding

Peacebuilding includes a wide spectrum of steps, processes, and means to limit and prevent violence and social injustice and to address destructive conflict in a nonviolent manner. During and following armed conflict, the central focus of peacebuilding is typically on nonviolent conflict management and resolution and reconciliation, which aims to improve relations between people and groups who had formerly been locked in destructive conflict. Conflict can be constructive when it is managed in ways that promote communication, healthy relationships, and a sense of positive interdependence (Deutsch et al., 2006). To handle destructive conflict nonviolently, psychologists have developed or refined numerous tools designed to resolve conflict and to transform or repair damaged relationships.

Negotiation, the handling of conflict through communication and bargaining by the parties themselves, has important psychological dimensions. If, as often occurs in official diplomacy between hardened adversaries, opponents view negotiation as a win–lose affair, they may dig into entrenched positions and use damaging, coercive tactics such as threats. Psychologically, a more useful alternative is principled negotiation, which reframes negotiation as a win–win affair. In this approach, parties collaborate to solve their problems and seek not to beat the opponent but to enable all parties to meet their underlying needs, thereby contributing to improved communication, empathy, and relationship. Negotiators vary considerably in which approaches they take and in when and how they express and use emotion. Which approaches to negotiation are likely to succeed depend not only on the situation, the kind of issues at stake, the amount of fear and relational damage but also on culture. For example, US negotiators favor direct communication and emphasize what is said, while Asian negotiators often communicate indirectly, relying on context and maintaining group harmony by avoiding direct confrontation.

Strong mistrust, fear of appearing weak, and poor communication can make negotiation infeasible. In this situation, a preferred approach is mediation, in which a third party helps the parties to negotiate a settlement. By proposing alternatives that the parties may not be willing to suggest themselves, mediators enable face-saving. They may also use social influence processes such as 'carrots and sticks,' a mixture of promised rewards for conflict reducing steps and promised punishments for intransigent behavior. Skilled mediators manage the conflict process, separating the parties when they are likely to say or do damaging things.

Official diplomacy, however, is limited since hardened adversaries may be unwilling to meet publicly. Also, public agreements can evoke backlashes, and official treaties may not change the polarization, fear, and hostility present in divided societies and communities. Herbert Kelman (2005) has pioneered the use of interactive problem-solving workshops as a tool of unofficial diplomacy and relational improvement. Regarding the Israeli–Palestinian conflict, a typical workshop brings together three to six Israelis with an equal number of Palestinians for 3 days of private dialog facilitated by social scientists. The participants are people of rising influence in their respective societies who may subsequently move into official positions where they can influence policy directly. Aside from influencing rising leaders, however, the workshops have a dissemination function in which the participants share their learning with others in their communities, thereby influencing civil society and attitudes.

In analytic, problem-solving discussion, the participants examine the main issues at stake in the conflict, explore their concerns and fears, and identify possible steps and solutions that could reduce the political and psychological barriers on both sides. Empathy, problem-solving, and group exploration of 'what-if' questions are encouraged. By conducting the workshops in private and in academic settings where norms of truth-telling and political nonalignment are prominent, the workshops permit reflection outside participants' ordinary contexts, which are highly politicized, and give them freedom to think 'off the record' and to build productive relationships with participants on the other side. Afterward, participants take their new learning about the other side back into their communities, beginning the wider process of community transformation. By building positive relationships and infusing

useful ideas into conflict-torn communities, this method provides a useful complement to official negotiation.

Positive contact between members of polarized, isolated groups can also reduce destructive conflict (Pettigrew and Tropp, 2011). Positive contact is likely to occur in a context of equal status that enables individuals to get to know each other personally and with steps having been taken to gain leaders' support and prevent damaging behavior. To reduce perceptions that the positive individuals from the out-group are exceptions, one may use cognitive strategies that enable generalization. One useful strategy is to build superordinate group identities, as witnessed in postapartheid South Africa when blacks and whites forged larger identities as 'South Africans' and championed the national rugby team.

The most powerful form of cross-group contact involves cooperation toward the accomplishment of shared goals that neither group could achieve on its own. This approach is called the superordinate goals strategy. Following the brutal, decade-long war in Sierra Leone that ended in 2002, this strategy was used to enable the community reintegration of young men who had been part of the rebel group that had attacked and looted villages. Groups of ex-combatants and other vulnerable youth worked together to build schools, health posts, and other community-selected projects, learning valuable economic and life skills in the process. Their cooperation reduced their enmity, built positive relations with community members, and enabled the social acceptance of the former fighters (Wessells, 2006). Global problems such as nuclear proliferation, environmental destruction, and the HIV/AIDS pandemic provide many possibilities for cooperation on shared goals that mitigates and prevents destructive conflict.

Work on postconflict peacebuilding has recently evolved away from a concern with the management or resolution of specific conflicts toward conflict transformation (Lederach, 1995), which seeks to change the relationships and societal beliefs, norms, and structures within which particular conflicts arise. The emphasis on conflict transformation is appropriate following armed conflict since the goal is not merely to stop the fighting and return the society to the prewar condition, which contained the seeds of conflict. Conflict transformation recognizes that particular conflicts are often manifestations of underlying causes of conflict that, left unaddressed, will likely spawn new conflicts. An important underlying source of destructive conflict is social injustice.

Social Justice and Prevention

Psychologists' promotion of peace frequently entails work on diverse aspects of justice. Distributive justice has to do with social equity and the equal distribution of and access to resources such as money, health care, education, voting privileges, and political power. Restorative justice entails making amends for social transgressions or repairing the harm caused by objectionable behavior such as criminal actions and human rights violations. Restorative justice contrasts with retributive justice, which seeks retribution for harms done, typically through the denunciation of crimes and the imposition of stiff penalties. This section emphasizes distributive and restorative justice since retributive justice frequently involves an 'eye for an eye' approach that sits uneasily with values of peace. Also, retributive justice often models the violence that peace promoters seek to prevent.

Transitional Justice

Although emergencies such as armed conflicts typically take a heavy toll in individuals and societies, they may also present opportunities for constructive social change. To promote justice and peace following mass atrocities and injustice, many societies have created transitional justice processes that may include truth processes and means of establishing justice (Hamber, 2009). Transitional justice processes have been constructed in diverse postconflict societies such as South Africa, Rwanda, Sierra Leone, Liberia, Cambodia, Philippines, Chile, and El Salvador, among others. Although these processes vary significantly across contexts, they seek in general to uncover the truth about the past and to end the impunity that encourages perpetrators of human rights violations. Psychologically, truth telling aims to bring hidden violations against people to light, give survivors a voice, and remind them that they are not alone, and, enable the families of those who had been detained, tortured, attacked, raped or killed to achieve closure by learning what happened to their loved ones. Justice mechanisms vary yet often enable public hearings that put perpetrators on the stand, invite public apology and expressions of remorse for wrongs that had been done, and provide reparations for people who had suffered or been harmed.

A useful example of both the promise and the complexity of such processes is the Truth and Reconciliation Commission (TRC) of South Africa. The postapartheid government of South Africa initiated the TRC as a means of dealing with the previously hidden pain and injustice inflicted by the state terrorism of the apartheid regime, correcting falsifications of history, and enabling forward movement toward social equality. Chaired by Archbishop Desmond Tutu, the TRC worked through three committees: the Human Rights Violation Committee, the Reparation and Rehabilitation Committee, and the Amnesty Committee. With hearings conducted in diverse places, thousands of victims of rights abuses that occurred between 1960 and 1994 told their stories and in some cases confronted the perpetrators, who were granted amnesty in exchange for telling the full truth. The plan was to provide reparations for the survivors of injustices as a means of enabling their rehabilitation.

The evidence regarding the effectiveness of the TRC has been mixed. Supporters have noted that the process helped to uncover the injustices and wounds of the past and to enable national healing and movement toward a new South Africa in which racism was unacceptable. Also, as survivors told their harrowing stories and cried, they were supported and affirmed by the members of the TRC. Some survivors who testified said that they felt better having told their story, brought the violation of their right to light, and publicly confronted the perpetrator. The public nature of the hearings, which were televised, was seen as beginning a process of healing and reconciliation that would enable equal participation of people of diverse ethnic backgrounds in the new South Africa. Through the work of the Reparation and Rehabilitation Committee, which was headed by a psychologist, the TRC organized a mix of communal and individual reparations, thereby reducing problems of favoritism, stigmatization of survivors, and social

divisions. Internationally, the TRC was instrumental in legitimating the new order and transforming the images of South Africa, which had been denigrated during the apartheid era as a highly racist, unethical society that was best dealt with through severe sanctions.

The effectiveness of the TRC, however, was limited in numerous respects. Some of the survivors who testified reported that the perpetrators may have told the truth but showed no remorse, without which amnesty seemed inappropriate. Doubts were also expressed about the accuracy of some of the perpetrators' testimonies, particularly since amnesty was not granted for the most severe offenses and it was in perpetrators' interest to not disclose their most egregious crimes. Although the TRC had granted amnesty sparingly to perpetrators on both sides, the South African military stood outside the process, despite evidence that the military had committed significant violations. In addition, some survivors who testified reported that they felt better having done so, whereas others said they did not or had felt used. Large numbers of survivors were unable to testify through the formal TRC process and participated instead in nonformal community processes organized through groups such as Kulumani. Many survivors who had testified in the TRC were frustrated and upset that although they had told their stories, they and their families continued to live in conditions of extreme poverty and deprivation. The inability to provide extensive economic reparations on a wide scale also limited the effectiveness of the TRC.

Despite these limits and complexities, processes such as the TRC are best viewed as springboards for additional work on social reconstruction for peace. In many societies that have engaged in transitional justice processes, the gains have come less from the specific outcomes of the formal process than from the societal reflection, dialog, and transformation that had accompanied and followed it.

International Criminal Court

The International Criminal Court (ICC) was established in 2002 as a permanent tribunal under international law that prosecutes perpetrators of genocide, crimes against humanity, and war crimes. In contrast to the restorative justice approach of many transitional justice processes, the ICC takes a retributional approach that not only punishes individuals for their crimes but also seeks to build norms of justice by ending the impunity that is frequently associated with human rights violations. The ICC engages with forensic psychologists on a regular basis. Also, clinical psychologists have helped to provide emotional support for survivors who have taken the stand, where they may be forced to relive very painful experiences and where their testimony may place themselves or their family members at risk.

In the case against Thomas Lubanga, the former commander of an armed group in the Democratic Republic of Congo, the ICC made in 2012 its first conviction of a person on charges of having recruited children under the age of 15 years as soldiers. Psychological expert testimony supported the case against Lubanga, arguing that children's participation in an armed group may have powerful psychological effects.

There is debate, however, about whether this type of conviction and work supports justice and peace. Proponents point out that the case draws a line against child recruitment and may deter potential child recruiters in the future. Also, they note that children's exploitation as soldiers is globally one of the enablers of armed conflict. Critics, however, have argued that the ICC has focused excessively on child recruiters in Africa, whereas child recruitment occurs in many different regions. Also, some analysts have expressed concerns that the retributive justice meted out by the ICC sets a bad example and in some contexts, undermines the peace that might have been achieved through the pursuit of less formal mechanisms. For example, the ICC had also brought charges against Joseph Kony in northern Uganda for crimes against humanity committed via his so called Lord's Resistance Army. Significant sentiment in northern Uganda held that such legal prosecution by outsiders made it difficult to pursue the deeper, indigenous peace process that was needed in northern Uganda, where the conflict had taken place. It remains for future research to determine the long-term effects of the ICC process, which are influenced by multiple rulings, and the most roles and the effective balance of formal and informal processes in contributing to peace.

Advocacy for Social Justice and Human Rights

In many countries, psychologists have been active in advocating policies aimed at ending social injustice in the form of 'isms' such as racism, sexism, and militarism. For example, in the US, racism was deeply entrenched in public life long after slavery had ended. In the South, blacks experienced systematic discrimination through Jim Crow laws that were backed by the ongoing threats of violence. Discrimination was prominent in public education, which was segregated into white and black schools, respectively, under guidance of an 1896 Supreme Court ruling (*Plessy vs Ferguson*) that accepted the idea of 'separate but equal.' In opposition, distinguished psychologists such as Kenneth Clark gave expert legal testimony that segregated schools imparted a sense of inferiority to black children. This testimony is widely seen as having helped to motivate the Supreme Court ruling in 1954 (*Brown vs Board of Education*) that prohibited separate schools and mandated the desegregation of public education. It is noteworthy that this policy has not been backed by consistent social mobilization in favor of integrated schools. As a result, the implementation of the policy has faced numerous obstacles and has been uneven in its effectiveness.

Psychologists in diverse countries have also been active in addressing policy and ethics issues associated with torture and related human rights violations. Following the 9/11 terrorist attacks, for example, the US government enacted policies of rendition, detention without basic rights such as *habeas corpus*, and the use of harsh methods such as waterboarding, stress positions, and sleep deprivation in hopes of extracting intelligence information from people who were being detained under charges of being suspected terrorists. Reports of psychologists having advised on the interrogation of some detainees provoked much discussion and moral reflection in the profession of psychology. Organizations such as Psychologists for Social Responsibility contributed to efforts to change the ethics codes and policies of psychology organizations in ways that would prohibit psychologists from working in sites that operated outside of international law and from advising on or participating in the use of coercive interrogation methods that the International Committee of the Red Cross has

indicated are tantamount to torture. To prevent the misuse of psychology, psychologists worldwide are active in promoting international human rights standards as the basis for codes of professional ethics.

Peace Education

Social psychological analyses indicate that in different countries social learning processes teach values and behaviors that support violence in a mixture of intentional and unintentional ways. For example, parents who spank their children for disobedient behavior may not only suppress that behavior but also teach their children that physical punishment and violence is acceptable, even appropriate. At school, children may observe and imitate the violence seen in arguments, fights, and bullying, and boys in particular may be rewarded for behaving in ways regarded as masculine or tough. Through violent video games, films, and electronic media, young people may learn violent means of responding to conflict. Through war memorials and nationalistic media, children may learn to fear and hate national enemies and to see violence conducted by the military as honorable and necessary.

Peace education is a means of socializing children for peace and of preventing violence and social injustice. Peace education may occur formally through activities in schools, yet also occurs informally at home, among peers, in the community, and in the wider society. Broadly, peace education enables learning that supports values and behavior that promote nonviolence and social justice. Peace education nurtures empathy, compassion, and a sense of social interdependence; builds specific skills of handling conflict through nonviolent means; and promotes social justice.

Psychologists contribute to peace education by being positive role models, using methods of constructive controversy to enable critical thinking, stimulating reflection and learning that undermines stereotypes of other groups, and analyzing effective ways of teaching and learning the values and skills that support nonviolence. Extensive psychological research has focused on cooperative learning, in which students collaborate in school to solve problems or complete assignments. Compared to competitive efforts by individual students, cooperative learning typically produces higher levels of productivity and achievement, increased cohesion and positive relationships among students, and increased self-esteem, psychological well-being, and ability to cope with adversity (Johnson et al., 2008). Similarly, psychologists have helped to develop means of measuring the psychological impact of various peace education activities, programs, and curriculi.

Viewed in this manner, peace education is both transformational and systemic. It is transformational because it seeks to prepare people to promote peace and social justice rather than to reproduce socially constructed patterns of violence and injustice. It is systemic since it seeks to promote ongoing learning for peace at levels that engage individuals, families, communities, mass media, and entire societies. Through peace education and the other activities discussed in this article, psychologists seek to do their part to transform current systems of violence into systems of peace.

Abstract

Karl Pearson had a successful career as a physical scientist before turning to the biological sciences. He published comparatively little on the social and behavioral sciences but his influence was considerable for he was the first modern statistician. Although some of the aspirations and even some of the methods of modern statistics can be traced back centuries, the modern discipline took off at the end of the nineteenth century. Karl Pearson contributed to the take-off by identifying problems amenable to statistical treatment, by developing appropriate techniques and by laying the foundations of a discipline. Some of his contemporaries did some of these things better, but none combined them so effectively.

Karl Pearson published extensively on the physical and biological sciences and comparatively little on the social and behavioral sciences, but to the latter he contributed the modern role of *statistician*. While some of the aspirations and even some of the methods of modern statistics can be traced to the seventeenth century, it is generally held that the modern discipline took off at the end of the nineteenth century: see Stigler (1986) and Hald (1998). To the take-off Karl Pearson contributed by identifying problems amenable to statistical treatment, by teaching influential practitioners and by creating the infrastructure needed for a discipline including university departments, courses, laboratories, journals, statistical tables; for Pearson's influence on economists see Aldrich (2010) and, for infrastructure, Magnello (1999) and Aldrich (2013). Some of his contemporaries did some of these things better, but none combined them so effectively. There is an annotated bibliography of Pearson's writings by Morant (1939) and there is now an extensive secondary literature surveyed by Aldrich (2011). The best overall account of Karl Pearson's life remains the *Appreciation* by his son E.S. Pearson (1936–38), but there is a rich study of the early 'KP' by Porter (2004).

Life

Karl Pearson was born in London, the son of a successful lawyer, but he was always proud that his ancestors were of Yorkshire 'yeoman stock.' Karl was a delicate child but he thrived at Cambridge University, where he studied mathematics. Success in the examinations brought him a fellowship and for a few years the financial freedom to pursue his very wide interests. Pearson qualified as a barrister and studied social, philosophical, and historical issues. He developed his own view of man's place in a post-Christian world, expressing this in a novel and a play as well as through essays, some of those were collected in the volume *Ethic of Freethought* (1888).

In 1884, the essayist and freelance lecturer became professor of applied mathematics and mechanics at University College London, where he would remain for the rest of his life. In his early days at the College, Pearson took on two books left unfinished when their authors died. W.K. Clifford's *Common Sense of the Exact Sciences* explained the nature of mathematics and for Pearson it would serve as a bridge from his early general essays to his *Grammar of Science* (1892). The *Grammar of Science* presented the scientific method as "the orderly classification of facts followed by the recognition of their relationship and recurring sequences." In later editions, the positivist ideas about space and force were joined by an exposition of statistical ideas. The other book, Isaac Todhunter's *History of the Theory of Elasticity*, was the history of Pearson's own specialism and Pearson actually wrote much more of this vast work than Todhunter himself. Pearson's later historical researches – a biography of Galton and lectures on the history of statistics – would combine Todhunter's thoroughness with his own interest in broad intellectual currents.

In his mid-30s, the elastician with philosophical interests took up biometry and statistics under the influence of his colleague W.F.R. Weldon. Weldon had joined the College in 1890 as professor of zoology and was already applying Francis Galton's statistical methods to the formation of species. Pearson helped Weldon extend the methods, but he was not just a mathematical consultant, he became a contributor to the biological literature in his own right. The partnership with Weldon was central to Pearson's development and he made his most important contributions to statistical thinking in these early years with Weldon. Pearson wrote over 300 pieces after 1900 but they were on lines he had already established. These works demonstrated what statistical methods could achieve and contributed to making statistics a recognized discipline.

In 1901, Pearson, Weldon, and Galton founded *Biometrika*, a 'journal for the statistical study of biological problems,' which published empirical studies, tables, and some statistical theory. From 1903, a grant from the Worshipful Company of Drapers funded the Biometric Laboratory. The laboratory drew visitors from all over the world and from many disciplines. Pearson wrote no textbook or treatise but the visitors passed on what they had learned when they returned home and they could keep up to date by reading *Biometrika*. In 1907, Pearson took over a research unit founded by Galton and reconstituted it as the Eugenics Laboratory. This laboratory researched human pedigrees, but it also produced controversial reports on the role of inherited and environmental factors in tuberculosis, alcoholism, and insanity – great topics of the day. One of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61105-4

Pearson's projects was to create a scientific basis for eugenics; see Kevles (1985). In 1911, a bequest from Galton enabled Pearson finally to give up responsibility for mechanics and applied mathematics and become professor of eugenics and head of the department of applied statistics. During World War I, normal activities virtually ceased but afterward expansion was resumed. However, Pearson was no longer producing important new ideas and Ronald Fisher was supplanting him as the leading figure in statistics. Pearson retired in 1933 but he continued to write and, with his son Egon S. Pearson, to edit *Biometrika*.

Pearson made strong friendships, notably with Weldon and Galton, but he also thrived on controversy. Some of the encounters produced lasting bitterness, those with William Bateson and Ronald Fisher being particularly unforgiving. Following the 'rediscovery' of Mendel's work in 1900, Bateson questioned the point of investigating phenomenological regularities such as Galton's law of ancestral heredity. The biometricians replied that such regularities had been established and that any theory must account for them. The quarrel about the value of biometric research faded with Weldon's death in 1906 and Pearson's gradual withdrawal from research into inheritance; the controversy is reviewed by Provine (1971). Fisher, like Bateson, was a Mendelian, but he agreed with Pearson on the importance of the statistical method. Fisher found fault with the execution of Pearson's statistical work, but he also judged that Pearson abused his commanding position in biometry.

Contributions to Statistics

For Pearson, empirical research and methodological innovation went hand in hand and his empirical work was always serious: he wanted to make a contribution to knowledge in the field to which he was applying his methods as well as showing that they 'worked.' However, his contributions to statistical methodology overshadowed his contribution to any substantive field and his scientific reputation rests upon them. It is convenient to divide his statistical contributions into ways of arranging numerical facts – univariate and multivariate – and methods of inference – estimation and testing.

Univariate Statistics: The Pearson Curves

Pearson's first major statistical paper (1894) was on extracting normal components from 'heterogeneous material.' Pearson was not, however, an admirer of the normal distribution or of the 'theory of errors' for which it provided the basis. For him the usual phenomenon was 'skew variation in homogeneous material' and this called for additional distributions, and Pearson (1895) presented a system of frequency curves, which would be of use in 'many physical, economic, and biological investigations.' Systems were also developed by Edgeworth, Charlier, Kapteyn, and others, but Pearson's was the most widely used. Other systems have been devised, inspired by his, but none has been as central to the statistical thought of its time.

From probabilistic considerations – which now seem contrived – Pearson obtained a basic differential equation governing the probability density function, or frequency curve, $y = y(x)$:

$$\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{y(x+a)}{b_0 + b_1 x + b_2 x^2}$$

The constants determine the form of the curve. Pearson developed methods for choosing an appropriate curve and for estimating the constants. From his laboratory came tables to ease the burden of calculation.

While Pearson used these curves as data distributions, he assumed that the estimators of the constants would be approximately normal, certainly in the large samples he generally worked with. In the work of 'Student' (W.S. Gosset of Guinesss) and especially Fisher the data distributions are normal but the exact distributions of the sample statistics are usually not, though *they* may follow a Pearson curve. 'Student' did his distribution work in Pearson's laboratory, but for many years Pearson thought that such 'small sample' work was off the main track and of interest only to 'naughty brewers.'

In the Pearson system the normal distribution is just one type. In Fisher's analysis of variance, which appeared in the 1920s, it is the *only* type. Workers schooled in the Pearson system did the earliest robustness studies and one of the continuing roles of the system has been in this area. While Pearson's skepticism toward normality pervades much modern work, the modern approach to inference is so different from his that he is not a direct inspiration.

Multivariate Statistics: Correlation and Contingency

In 1888, Galton introduced correlation and soon Edgeworth was developing the theory and Weldon was applying the method in his research on crustaceans. Pearson, however, produced the definitive formulation of normal correlation and had the vision that correlation would transform medical, psychological, and sociological research.

Pearson (1896) set out to frame hypotheses about inheritance in terms of the multivariate normal distribution but these were of less enduring interest than his account of correlation and multiple regression. The familiar partial and multiple correlation and regression coefficients appeared at this time either in Pearson's work or that his assistant, G. Udny Yule. Soon, Pearson and those around him were applying correlation in meteorology, sociology, and demography, as well as in biometry.

The 1896 ideas formed the basis of a definitive theory, especially when completed by the exact distribution theory of 'Student' and Fisher. But Pearson soon moved on to qualitative, nonnormal, and time series data, though not with the same success. Pearson's scheme for contingency, the qualitative analogue of correlation, has latent continuous variables – surprisingly jointly normal ones. Yule, no longer working with him, rejected the scheme; the controversy has been studied from a social studies of science perspective by MacKenzie (1981). Pearson toiled unsuccessfully to create a theory of skew surfaces, uniting correlation and skew curves.

Time series correlation analysis was another disputed field. Pearson thought of the true correlation between series as obscured by time trends superimposed upon them. The scheme was widely used, but in the 1920s Yule criticized it effectively without putting anything in its place.

From the beginning Pearson encountered problems with correlation that have lived in the underworld of statistics, occasionally surfacing in fields such as path analysis and structural modeling. Pearson formalized Galton's notion of correlation as measuring the extent to which variables are governed by 'common causes.' He was soon aware of cases of 'spurious correlation,' where the natural interpretation is not sustainable. He and Yule – who developed the other standard interpretation of a direct causal relationship between the correlated variables – found numerous pathological cases. They devised treatments but developed no systematic way of thinking about the problem.

Pearson – following Galton – established multivariate analysis. Yet, by a curious twist the multivariate data for which Pearson struggled to create a theory of frequency surfaces are often treated by Fisher's 'regression analysis,' which was a development from Gauss's (univariate) theory of errors rather than from Pearson's correlation theory.

Estimation: The Method of Moments and Inverse Probability

Pearson usually found the constants of frequency curves by the method of moments. He introduced this in his first major paper (1894) for he could find no other method for estimating a mixture of normals. Pearson went on to apply the method quite generally. It seemed particularly appropriate for the Pearson curves where the constants determine the first four moments. However, the method was put on the defensive after Fisher criticized it for not being 'efficient' – even when applied to the Pearson curves.

Probable errors (scaled standard errors corresponding to the 50 percent point) for method of moments estimators were derived by Pearson and Filon (1898) using a modification of an argument in the 1896 correlation paper. Pearson had obtained the product-moment estimate from the posterior distribution (based on a uniform prior) and its probable error from a large sample normal approximation to the posterior. In 1898, he assumed that the same technique would always yield probable errors for the method of moments. He seems to have dropped the original technique when he realized that the formulae could be wrong but it was reshaped by Fisher into the large sample theory of maximum likelihood.

In 1896–98, Pearson used Bayesian techniques quite mechanically but he could also be a thoughtful Bayesian. Over a period of 30 years he wrote about the 'law of succession,' the standard Bayesian treatment of predicting the number of successes in future Bernoulli trials given the record of past outcomes – 'the fundamental problem of practical statistics' he called it. Pearson held that a prior must be based on experience; a uniform prior *cannot* just be assumed. Pearson pressed these views in estimation only once when he criticized Fisher's maximum likelihood as a Bayesian method based on an unsuitable prior – essentially Pearson's own method of 1896–98. Fisher was offended by this misinterpretation of his Bayes-free likelihood analysis.

There was plenty of improvisation in Pearson's estimation work; it was eclectic, even inconsistent. He was not the consistent Bayesian that Harold Jeffreys would have liked. Pearson used sampling theory probable errors, but he did not follow up the results on the properties of estimators in the old theory of errors. Pearson was not unusual in his generation; the theory of errors he found to hand mixed frequentist and Bayesian arguments. Some of his contemporaries were more acute but foundational clarity and integrity only became commanding values toward the end of his career when Fisher, Jeffreys, and Neyman set about eliminating the *wrong* kind of argument.

Testing: Chi-Squared

Pearson's earliest concerns were with estimation – curve fitting and correlation – though their testing could be done using the estimates and their probable errors and making the assumption of large sample normality. However, his chi-squared paper of 1900 introduced a new technique and gave testing a much bigger role.

The chi-squared test made curve fitting less subjective. One could now say: "In 56 cases out of a hundred such trials, we should on a random selection get more improbable results than we have done. Thus, we may consider the fit remarkably good." The tail area principle was adopted without any examination. Naturally, Pearson, the critic of the theory of errors, enjoyed showing that the fit of the normal distribution to errors in astronomical measurements was *not* good.

Pearson brought chi-squared into his treatment of contingency and by 1916 he had established the main applications of the chi-squared distribution – a test for goodness of fit of distributions, a test for independence in contingency tables, a test for homogeneity of samples, a goodness of fit test for regression equations.

Pearson's distribution theory involved the exact distribution of the exponent in the multinormal density, this density appearing as a large sample approximation to the multinomial. Pearson slipped in the mathematics and used the same approximation whether the constants of the frequency curves are given a priori or estimated from the data. Fisher realized the importance of the difference and reconstructed the theory, finding that the chi-squared approximation was valid but the number of degrees of freedom had to be altered.

Fisher continued Pearson's chi-squared work and gave significance testing an even bigger role in applied statistics. Pearson's methods were more or less vindicated by the later work of Fisher and then of Neyman and E.S. Pearson but, as in estimation, his reasons did not pass critical examination.

Summary

Of the many statistical techniques Pearson devised, only a few remain in use and, though his ideas sometimes find reexpression in more sophisticated form, such as the correlation curve or the generalized method of moments, there is little to

suggest that Pearson continues to directly inspire work in statistics. Pearson broke with the theory of errors but in the next (Fisher) generation the theory was restored through the analysis of variance and regression to stand beside and even overshadow Pearsonian statistics. From a modern perspective, Pearson's inference theory seems desperately superficial. Yet, the problems he posed have retained their importance and the ground he claimed for the discipline of statistics has not been given up. Appropriately, the sesquicentenary of Pearson's birth was marked by both the Royal Statistical Society and the International Statistical Institute – for the latter, see Seneta and Stamhuis (2009). Ironically, Pearson never belonged to either body for he scorned their lack of scientific credentials and it is a mark of his effect on statistics that the modern bodies should recognize *him* as an honored ancestor.

Peasantry in the Twenty-First Century

Abstract

The deregulation of markets and the increasingly interlinked global markets make it very difficult for small farmers to survive. Thus, small primary agricultural producers must search for new ways to continue farming and earn a reasonable income. In many places, this has triggered a process of repeasantization that is reversing the once seemingly inevitable processes of modernization and urbanization. This article argues that this process occurs through six mechanisms that together have a strong impact on the nature and dynamics of the process of agricultural development.

Both the social and academic conceptions of what a peasant is extend beyond that of someone just involved in agricultural activities. Being a peasant is more than just being a producer of food or other agricultural products. True, peasants are involved in agriculture, but they do so because it offers them a livelihood that provides them with employment, income, an identity, a place to belong to (which is also a relatively safe and clean space for their children to grow up), social networks, and, probably, some level of dignity and the feeling that they are part of a more comprehensive whole. It is difficult to find such a livelihood in the slums that abound in most of the big cities of the world. So for many, peasantry is the only realistic alternative. And when peasants engage in labor migration (often crossing national borders), this form of livelihood remains a critical and essential point of reference. Migrant peasant workers send much of what they earn back home in the form of remittances and cherish the hope and dream that someday they will return, even if only after many years, and invest their savings in their land. For them, their farm represents an important psychological and economic fallback position.

For peasants, their livelihood (that often includes faraway places) offers a starting point for improving their lives, albeit slowly and in a step-by-step way. It is the space in which they struggle for autonomy and improvements (van der Ploeg, 2008; Langthaler, 2012). They do so, mostly because this is the only way they have to respond to the dependency and deprivations they experience. Such struggles involve resistance, sturdiness, doggedness, and distrust of the outside world.

Peasants have specific and characteristic patterns of involvement in agricultural activities that differ, sometimes subtly, sometimes more obviously, from corporate or entrepreneurial ways of farming. Ecological capital and labor are central to peasant farming. Labor is used to convert living nature into valuable products. Peasant farming is labor intensive and is developed through labor-driven (as opposed to capital-driven) intensification. It aims to improve the value added that can be gotten out of the scarce available resources and to reproduce and develop these resources over time. Labor investments (in the further improvement of the resource base) are a powerful mechanism for growth and development in peasant agriculture.

Yet at the same time, peasant livelihoods are also vulnerable and are sometimes nearly suffocated by outside forces. Since peasant farms operate in at least four different markets (for inputs, agricultural produce, labor, and consumption goods), they can run considerable economic risks. In addition, their farming practices may be prone to uncontrollable climatic risks and a range of natural disasters. Finally, their power relations with the surrounding society are often weighted against them and can pose the threat of dispossession (through, for example, land or water grabbing or legal suits about property rights to genetic material).

For decades it has been assumed (and continuously argued) that farming-as-a-livelihood (i.e., peasant farming) is completely at odds with the entrepreneurial attitudes, growth, investments, and rationality of modern-day society. In short, farming-as-a-livelihood was equated with backwardness. And although some persist in making such arguments, it is now widely accepted among scholars of the rural (IAASTD, 2009; HLPE, 2013) that this is not the case. Peasant agriculture has the potential to be highly productive and efficient. Its yields are often considerably higher than those from other forms of agricultural production, and its output-to-input ratios reflect high levels of efficiency. In addition, peasant farming creates much employment and generates considerable incomes, thus contributing to the enlargement of the domestic (and particularly rural) market (which in turn may trigger other forms of economic growth, Haggblade et al., 2007). It can be a safeguard for sustainability and contribute to the emancipation of downtrodden social groups in society. Equally it plays a strong role in safeguarding biodiversity, scenic landscapes, and the attractiveness and accessibility of the countryside as a whole.

These potentials have been realized in many different places. This most often occurs when the political, economic, social, and cultural conditions – or "space" as Halamska (2004) phrased it – are favorable for peasant farming. If such space is lacking, peasant agriculture may well regress and perform poorly, and rural livelihoods become a synonym for poverty and an absolute lack of prospects.

During the last decades, peasant agriculture has faced a severe and long-lasting market squeeze. It has simultaneously suffered from high levels of market volatility, the effects of a decades-long neglect by states and multilateral organizations (as recently admitted by the World Bank; see McMichael, 2009), highly unequal terms of competition, lack of access to credit, and unequal power relations that create general insecurity and favor land and water grabbing. It is becoming

increasingly difficult for peasants to reproduce the farm and farm household solely by producing for the general markets for food and other agricultural products. However, peasants are not passive in the face of these many threats. On the contrary, they have, and are developing, an impressive range of responses to these many threats and finding new ways to (re)enlarge autonomy and (re)construct otherwise wrecked livelihoods. Analytically, we can identify six mechanisms that peasants have developed to reinvent their farms. These will be briefly discussed later. Such mechanisms are being deployed in both the Global South and in the Global North. The article also draws attention to the new modes of agricultural development that result from these reinventions. In this respect, it is important to note that overall agricultural development is always the aggregated outcome of different, and often mutually contrasting, development trajectories that coexist alongside each other. Hence, when peasant trajectories show positive results and large-scale capitalist farming show negative ones, the overall outcome might be zero. Overall tendencies might very well veil the value of peasant modes of agricultural development.

Reducing the Use of External Inputs

Contemporary agriculture can be characterized as having high (and growing) input levels. This is largely due to the introduction of technological models that built on the use of such *external* inputs. Most of these inputs replace internal resources: chemical fertilizers replace manure, green fertilizers, and a carefully nurtured soil biology; industrial concentrates replace feed and fodder grown on or near the farm; self-selected seeds are replaced by bought seeds, produced elsewhere; weeding is replaced by herbicides; etc. This also contributes to a kind of standardization: While internal inputs (i.e., produced and reproduced within the farm) are mostly highly adapted to local ecosystems, local ways of farming and in line with local knowledge, external inputs are far less aligned with local conditions, needs, and possibilities.

The increased use of external inputs (often combined into a 'package,' as was the case with the green revolution in the Global South and the *Holsteinization* of dairy herds in Europe) has undoubtedly helped to raise levels of productivity considerably – at least initially. Yet over time, these packages gave rise to new problems. The cost of acquiring these inputs was increasingly beyond the reach of many farming households. Hence, they needed credit, creating new financial and transaction costs, which continued to spiral. And, as production increased, farm-gate prices for produce started to decline. As a result, the costs of the external inputs utilized came to represent a growing proportion of the farm's total earnings.

This situation has triggered the first mechanism for reinventing peasant farming. Many farmers are returning to their neglected internal resources, trying to upgrade their quality, and simultaneously reduce the use of costly external inputs (Domínguez García, 2007; Paredes, 2010). This has the potential of bringing considerable cost reductions (while levels of production may remain the same or even increase). Beyond that, for many farmers, this change represents a return of the 'joy of farming.' Instead of simply applying the scripts developed by the agricultural sciences and brought to them in the form of external inputs and manuals (that specify how, when, in what sequence, by whom, and in which combinations these inputs should be used), farmers are again trying out things for themselves, experimenting and developing new local knowledge.

A good European example is the rediscovery of manure. This internal input became, during the period of modernization, a waste product that stank and even had the potential to badly pollute the soils and waterways. Thus, increasing amounts of chemical fertilizers became necessary. Now, facing both an environmental and an economic crisis, many farmers are once again rebuilding manure into a highly valuable internal input, to replace chemical fertilizers. This is done through a range of ingenious adaptations, including the dietary regime of the animals, the storage of the manure, the use of straw in the cowsheds, and the way manure is spread on the fields (Reijs, 2007).

More generally, the reduction in the use of external inputs (and the technologies that make them necessary) is strongly linked to the (re)emergence of what European farmers know as the style of farming economically, in which the farmer seeks to minimize monetary expenses (Kinsella et al., 2002). Thus, peasant farms are reemerging and, while their form may be new, their dynamics and rationale are, without doubt, very much peasant-like.

In Central and South America a similar trend is occurring, although the key word here is agroecology (Altieri et al., 2011; Rosset and Martinez-Torres, 2012). Agroecology embodies three strongly interrelated elements: a new scientific view on farming, a new practice (characterized by low levels of external inputs), and a strong social movement that seeks more autonomy for peasants and new ways of farming (Toledo, 2011). Recently it seems that a fourth element is emerging: increased government support for agroecology (MDA, 2013).

In terms of aggregate agricultural development, these processes and practices are making a large contribution to new forms and levels of sustainability. These differ markedly from approaches that involve the imposition of end-of-the-pipeline solutions, the conventional way of addressing environmental problems.

Developing Multifunctionality

A second mechanism used by peasants to consolidate and strengthen their farms is the production of *new* services and *new* products (and the subsequent development of new market channels) that bring new income flows to their farms and households. The magnitude of these new income flows can compensate for, or even exceed, the decrease in income derived from conventional production.

The production of new products and services is best captured with the notion of multifunctionality. This refers to the farm having more than just one function, i.e., producing agricultural products (which, in conventional patterns, are mostly raw materials for agro-industries). The other functions of a farm can include energy production, water retention, the management of nature and landscape, increasing or safeguarding biodiversity, agritourism, afforestation, fish ponds, care facilities, and a range of classical forms of

diversification (such as organizing transport, leasing storage facilities, etc.). These nonagricultural activities (*sensu stricto*) are combined with the typical agricultural activities within the farm. Both types of activities use the same resource base. In addition to creating additional income flows, this also creates synergies that generate considerable additional economic benefits (Saccomandi, 1998), which strengthen overall household income.

The pursuit of multifunctionality may also involve converting conventional agricultural production into new forms that result in an *enlarged* value added (VA) per unit of end product, a shift which also strengthens the overall income at household level. Examples here are organic farming, the production of high-quality products and regional specialties (which, especially in Europe, encompass a wide and increasingly legally protected spectrum), on-farm processing, and direct marketing. Multifunctionality is now strongly developed throughout Europe. Chinese agriculture has always been multifunctional, but a bewildering array of new expressions is currently being constructed (Ye et al., 2010). Brazil has strong pockets of newly developing multifunctionality (Schneider et al., 2010), and the same approach has always been present in the Andean mountains. More recently, forms of multifunctional farming are also being constructed in parts of the USA (Joannides et al., 2001).

The development of multifunctional farms is a clear expression of resistance (Schneider and Niederle, 2010). The desire to remain in farming translates into highly visible forms of reinvention: multifunctionality involves replacing the monotony of standard farming practices by often surprising new rural enterprises. It contributes to the emergence of new modes of agricultural development, by reorienting agriculture to new social needs that originate in the cities, making agriculture more attractive again and, especially through agritourism and peasant markets, (re)linking it to consumers (Low and Vogel, 2011). Multifunctionality also helps to enlarge resilience and to slow down the rural exodus. It is especially important to note that multifunctionality is often used to support investments in food production *sensu stricto*, thus contributing to its resilience (de Rooij et al., 2013).

Embedding Farming in Multiple Job Holding

Another increasingly important mechanism for reinventing peasant farming is the growing engagement in what the Chinese call 'multiple job holding' (MJH). Peasants not only work within their own farm (be it in agriculture or other activities related with the multifunctional nature of the farm), they increasingly also have a job elsewhere (van der Ploeg and Ye, 2010).This might be far away (giving rise to complex movements through time and space) or nearby. In Europe, this phenomenon is also widespread. In 85% of Dutch dairy farms, the man or the wife (or both) has another job that provides them with at least one-third, and sometimes more than a half, of the household income. Thus, farming is increasingly becoming a 'part-time' phenomenon (as it is now often seen in the Netherlands).

For many decades it was thought that part-time farming or MJH is the first step in the process of a farm disappearing. It is becoming clear, though, that it is exactly the other way around. By embedding the farm in a larger portfolio of economic activities, within and beyond the farm, farm continuity and development become feasible. MJH assures a flow of resources (savings, remittances, but also new knowledge, new lifestyles, new urban contacts) from the urban toward the rural and thus helps to sustain farming. It strengthens the resilience of agricultural and rural development and slows down the rural exodus. Sometimes the effects go even further. For example, in China, migrant workers from Yi County started to bring glass noodles (processed sweet potatoes) as gifts for their bosses, friends, and relatives in the cities after every spring festival (which they spend in their villages). This led to the glass noodles becoming a well-known and highly appreciated product that now is central to multifunctional agriculture in several villages in Yi County (Wu et al., 2014).

The Retreat of Entrepreneurial Farming

For several decades entrepreneurial farming has been presented as the promise for the future, while peasant farming was understood as a remnant of the past. Thus, the transition to 'modern agriculture' became central to agricultural policies such as the Common Agricultural Policy in Europe, the Farm Bill in the USA, and many programs for 'integrated rural development' throughout Latin America and Africa. In Asia, the many green revolution programs carried a similar rationale.

One aspect of entrepreneurial farming is that much of its growth basically occurs through the takeover of other farms (their resources, quota, environmental rights, shares in subsidies, market share, etc.), which is financed through the banking system. Entrepreneurial farming makes less use of ecological capital and is highly reliant on the use of external inputs. This means entrepreneurial farming is basically a financial operation. It is about operating with money in order to make more money. With higher financial and transaction costs, the costs of production are increased and the margin (or VA per unit of end product) is relatively low. Because of the sheer size of these farms, the final income might be considerable. But this is only the case when prices remain more or less stable and at the required level.

In the past 15 years or so, deregulation and liberalization have created a new reality characterized by an accentuated volatility in prices. As empirical studies now demonstrate, the sudden price falls have produced a hitherto unexpected consequence, i.e., negative cash flows, which are particularly evident in large entrepreneurial farms. Farm-gate prices have fallen below the costs of production, and the high financial costs and the high levels of external input use (tied to previous choices on technology use) make it almost impossible to react to this dangerous situation. On the other hand, the smaller peasant farms have higher margins and are more flexible; so, in this respect, they are far less vulnerable. Initially, the agricultural banks refinanced the entrepreneurial farms that entered into difficulties, but since they have recently been obliged to increase their own liquidity (under the Basel III Accords), this is no longer the case. Consequently, many places of the world are witnessing

a demise in entrepreneurial farming. It is notable that it is the largest, most modernized, and highly specialized farms that have experienced the greatest difficulties, which have often proved insurmountable (Oostindie et al., 2013). These farms are mainly located in Denmark, the Netherlands, and other parts of northwestern Europe. Similar difficulties are being experienced elsewhere by those who attempt to continue with the green revolution approach. Indebtedness, high levels of environmental pollution, stagnating yields, and the unwillingness of banks to continue their credit lines are but some of the telltale signs that give rise to frustration and disappointment among producers. The entrepreneurial model is 'running out of steam.' Many farmers who still have the 'space' to do so are opting out of this approach and rebuilding their farms along more peasant-like lines. Others are far too entrapped in path dependency. They mostly go bankrupt or accept a very low income (selling the farm often is not a solution since debts often exceed the decreased value of the assets). All this contributes to making the aggregate agricultural sector in many countries more peasant-like, (see for Russia Mamonova et al., 2013) and, at the symbolic level, the entrepreneurial model has lost much of its appeal and legitimacy. Meanwhile, the peasant way of farming is coming to be understood as a strong institution and possibly the best guarantee for food security and food sovereignty (HLPE, 2013).

In terms of agricultural development, the demise of the entrepreneurial model means that agro-industry and the state have lost at least part of their authority to shape agricultural development. At the same time, self-regulation, the development, the use of common pool resources (Ostrom, 1990), and new institutional arrangements that link producers, consumers, and local authorities (Morgan and Sonnino, 2008; Perez, 2012) are on the rise.

Enlarging the Ranks

While the farming population of all OECD countries has significantly decreased in recent decades, in the Global South the number of peasant producers keeps growing. It is currently estimated that on a global level there are some 550 million peasant units of production. This is more than ever before in world history. Within this global panorama some telling episodes can be discerned. In Brazil, the Movement of Landless People (*Movimento dos Sem Terra*) is leading a massive flow of people from the *favelas* of the big cities or overcrowded rural areas who go and occupy large tracts of extensively used land, creating new peasant farms. Thus, between the last two agricultural censuses (1996 and 2006) the number of peasant farms grew by more than 400 000 units (MDA, 2009). Currently, the rural areas of Europe's Mediterranean countries are also witnessing an inflow of young people, partly supported by European and national policies. In China, a noticeable feminization of agriculture is occurring (Meng, 2014).

In brief, the composition of the populations economically involved in agriculture is changing in many parts of the world and, in some places, their absolute number is increasing. In terms of overall agricultural development this is highly important, not least because it helps to counterbalance rural aging (White, 2011).

Countering Big Capital

From a sociological point of view it is noteworthy that, for the first time in history, the world now has an organization, *La Via Campesina* (LVC, which translates as 'the peasant trajectory'), which has developed to become a truly global peasant federation. This is a well-coordinated agglomeration of many organizations and movements that operate at national, regional, and local levels (Borras et al., 2008). LVC gives a voice to those who would otherwise remain neglected in this world. It is one of the main forces resisting the processes of land and water grabbing around the globe. LVC is a strong advocate of agroecology (discussed above), which it considers as one of the main defense lines against big capital groups and their endeavors to conquer spaces and create new conditions for capital accumulation in the countryside. One of the themes that LVC has developed is the concept of 'food sovereignty,' often loosely defined as the right of people to decide on how they want the production, processing, distribution, and consumption of food to be organized. This represents a significant reintroduction of democratic principles and rights into the realm of food production.

Some of the main themes championed by LVC partly coincide with policies that are now emerging in different places, including the rural development policies that have been put in place in regions as different as the European Union, China, and Brazil (van der Ploeg et al., 2012). These policies seek to correct the negative, often destructive tendencies of the large commodity markets for food and agricultural products and provide the space for the different forms of peasant reinvention discussed in this article, which hold the key to generating new modes of agricultural development.

Peasants and Rural Societies in History (Agricultural History)

Abstract

Studies of peasants in history, rural history, have expanded in three waves. The first spanned the late nineteenth and first half of the twentieth centuries and was dominated by ethnology–anthropology, whilst the second was driven by economic and social history during the 1950s and 1960s. The third wave began in the 1990s and involved different disciplines, eventually developing into transnational studies. Some overarching discussions have concerned: ownership and the community, the market and commercialization, and productivity and farming systems. During recent decades, peasants as agents in historical change have been recognized.

The concept of 'rural societies' is based on the division between rural and urban. There is a historical dimension as well since the concept refers to societies dominated by rural areas, and thus relates to rural history. In fact, there have been some major advances in the historiography of rural history since the turn of the twenty-first century (Thoen and van Molle, 2006; Alfonso, 2007).

Terminology

Discussing the terminology is an important part of theory building in the social sciences. An obvious case concerns the term 'peasant.' From the 1950s there were intense discussions about its meaning, and a large body of literature was published in the decades that followed. The debate was largely limited to the Anglo-Saxon world since most languages other than English do not make a clear distinction between peasants and farmers. In German, for instance, the term *Bauer* can mean both peasant and farmer (Rösener, 1993). The most important contributions to the discussion were published from the 1950s to the early 1970s (Redfield, 1956; Wolf, 1966; Potter et al., 1967; Shanin, 1971). Peasant society was defined on two levels: (1) chronologically in relation to earlier and later types of social systems and (2) socially in relation to the overall social structure within which it existed.

The peasant society was seen as a partial society (i.e., a part of the larger social structure). This formed the basis of the chronological separation of peasants from what was called the 'tribal society,' or, in a more precise terminology, a prestate society. The emergence of the town was identified as a decisive change. Peasants either were obliged or chose to send their produce to the town. The formation of the state and state authorities also had a major impact since peasant society became more obviously subordinated and even alienated from a larger social system as such. To some extent, both these criteria can be said to represent the same change. Peasant society has also been described as part of an overarching socio-economic feudal system (*see also* Feudalism). The other chronological distinction that separates peasants and farmers has also been discussed. Not only do modern farmers produce for the market, but also their actions are profit driven and farms are managed in a commercial way.

In 1971, Teodor Shanin (in his *Introduction* to Shanin, 1971) summarized the discussion about peasant society and highlighted some of its distinguishing characteristics: the family farm as the basic unit of multidimensional social organization; land husbandry as the main means of livelihood directly providing for the major part of the consumption needs; specific traditional culture related to the way of life of small communities; and the underdog position, specified as the domination of the peasantry by outsiders.

Different aspects were emphasized in the discussion. Wolf regarded the relationship to the market as decisive, whilst Redfield emphasized peasant tradition. Marxists later joined the discussion by stating that when peasants act as a group with class consciousness, they become a class in themselves. The Russian peasant researcher Alexander Chayanov stressed that the preservation of the family was of fundamental importance to the peasant (Chayanov, 1966).

It also became increasingly clear that the specific historical situation had to be taken into account. Rodney Hilton noted that his definition of the English medieval peasant was specific to a particular part of Europe (Hilton, 1975). This has connotations with the so-called Brenner debate, which was brought about by Robert Brenner's article in 1976 and followed by a discussion in which many leading European historians took part. It started with comparisons between French and English peasantries, but gradually came to include more regions. Class structure and the relation to the market were key issues (Aston and Philpin, 1985; Hoppenbrouwers and van Zanden, 2001).

The concept of the peasant nowadays tends to be used in a comprehensive sense to include all those who grow crops or raise cattle, on a partially nonprofitable base, whilst being integrated into a larger social structure. The definition includes peasantries in societies where the production of foodstuffs requires the major part of the society's labor.

Another important conceptual distinction involves the gradual transition from agricultural history to agrarian history and rural history. The first journals and publications considered 'agricultural history' to be the most natural term. This placed farming and production in the center, although other topics were also addressed. In the mid-nineteenth century, it became more common to refer to 'agrarian history,' broadening the scope of the subject to all aspects involving the local, often agriculture-dominated, community. In the first volume of the

Agricultural History Review in 1953, G.E. Fussel presented a list of books and articles on 'agricultural history.' Next time such a list was presented, by Joan Thirsk in 1955, it was on agrarian history. She also in 1956 took the initiative to the project *The Agrarian History of England and Wales*. The German term *Agrargeschichte* is quite broad, whilst the French concept of *études rurales* is even more inclusive.

In 1990 a new journal entitled *Rural History* was launched, to a degree in opposition to what was labeled 'cow and plow history.' It sought to link social, economic, and even cultural history to achieve a broader perspective. This partly reflected the 'cultural turn' in history writing as such, and partly it was just one stage in the long process of broadening this area of research.

Before World War II

Systematic research into peasants and rural history began at the end of the nineteenth century, and tended to focus on peasants in their own countries. Citizens of the United States perceived their country as an agricultural nation, and hence it followed that agricultural history was considered a subject of national interest. This soon crystallized into a discipline in its own right. The oldest journal on the subject, entitled *Agricultural History*, was founded in the United States in 1927. Whilst articles published in this journal have included subject matter from outside the United States right from the very beginning, the focus has largely been on American agricultural history.

In Europe, agricultural history was linked with the formation of national identity, as demonstrated by various national 'agricultural museums.' In Hungary, an agricultural museum was founded in conjunction with the country's millennial celebration in 1898. Similar museums were established in Denmark and the former Czechoslovakia at the same time. The second oldest journal in the agricultural history was associated with the National Museum of Agriculture in Czechoslovakia (*Věstník Československého Zemědělského Muzea* (1928–43) and Vědecké Práce Zemědělského Muzea (1961-onwards)).

Widening the perspective from rural history as such, folk-life studies (ethnology) focused on peasants, who were regarded as representing the real heart of the nation. Folk-life studies became common in Eastern Europe, Scandinavia, Germany, France, Portugal, Ireland, Scotland, and other countries and regions. The research focused on both spiritual and material culture, including folksongs and riddles as well as tools and houses. Even if the original goal was to use ethnology as a way to understand national identity, the opposite was increasingly found to be true. Instead of a folk culture separating and uniting the nation, it was found that every region and nation existed in a flow of influences. Cultural phenomena moved freely across borders. When a national identity was built on ethnology, often referring to the peasants, it had to be invented; Germany in the 1930s is the typical case (though we also have others). A number of national atlases on peasant society and its manifestations were published, yet unfortunately no all-encompassing European atlas was produced.

In countries with colonies, in particular the United Kingdom, the study of peasant societies outside Europe became increasingly popular at the end of the nineteenth century. Originally, these studies were part of the colonial administration (e.g., the genre of studies focused on the Indian countryside that developed during the nineteenth century). Eventually, social anthropology developed into a discipline in its own right. The purpose of these studies was to understand the local community, with a focus on a village or a region. However, they gradually pointed to a different result. It was increasingly realized that local society was integrated with, and subordinate to, larger social structures. This sparked the aforementioned debate on the definition of the peasant concept.

In Europe, the first wave of interest in the history of agriculture, ethnology, and anthropology focused on the immediate past. At that time history, as a discipline, was still mainly oriented toward the nation state and the elite classes. Rural history studies first developed in France under the influence of geography, where a dominating group of scholars favored all-embracing studies where every aspect of a region should be described, including history. The historian who succeeded in giving rural history a solid base was Marc Bloch with his publication *Les caractères originaux de l'histoire rurale française* (*French Rural History*), which appeared in 1931 (Bloch, 1966). It was based on a series of lectures that he had held at the Institute for Comparative Research in Human Culture in Oslo in 1929, which had been established to promote folk-life studies.

Bloch's work still provides inspiration and guidelines to a number of areas: the role of the village community, peasant uprisings, the links between technology and social change, and so on. However, it was not until after World War II that his books garnered widespread recognition.

Breakthrough after World War II

The subsequent success of Bloch's work needs to be explained in terms of the changes that took place in the study of history. During the two decades following the end of World War II, agricultural history became a discipline in its own right in Western Europe. In the 1950s agrarian or agricultural history groups were established at several universities across Europe: at the University of Wageningen (Netherlands), the University of Hohenheim (Germany), and the University of Reading (United Kingdom).

A number of national European journals were also founded at this time. In the major languages we have the *Agricultural History Review* (1953–) in the United Kingdom, *Zeitschrift für Agrargeschichte und Agrarsoziologie* (ZAA) (1953–) in Germany, and *Études rurales* (1961–) in France. Other journals were published in the Netherlands (1953–), Denmark (1956–), Hungary (1957–), and Italy (1961–). The aforementioned Czech journal at the agricultural museum was relaunched in 1961, and a similar journal came in Bratislava (Slovakia) from 1962. The German journal *ZAA* in 1954–57 published historiographical essays on agricultural history in France, the United Kingdom, Scandinavia, and Poland, written by (for instance) Georges Duby and Joan Thirsk.

In time, national syntheses comprising several volumes were published. The German *Deutsche Agrargeschichte* consists of six volumes and was published between 1962 and 1984. The *Histoire de la France rurale* was produced between 1975 and 1978,

which comprises four volumes. *The Agrarian History of England and Wales* was published in several volumes from 1967 to 2000, and it remains one of the largest national history projects ever conducted, comprising a total of over 9000 pages.

This wave of research had an increased focus on long-term change, not least with respect to the Middle Ages. Two important works were published in the early 1960s. One was George Duby's *L'économie rurale et la vie des campagnes dans l'Occident medieval* (it was published in French in 1962, and the English translation appeared in 1968). In 1963, B. H. Slicher van Bath published *The Agrarian History of Western Europe A.D. 500–1850*, which had originally appeared in Dutch in 1960.

The agrarian crisis of the late Middle Ages became a central field of research in economic and social history. Although this economic decline had already been observed prior to the World War II (in Germany, Norway, and the United Kingdom), it did not gain general acceptance until the 1950s. The discovery was theoretically significant since it showed that the development of production and population had not always been positive.

Another important theoretical change was that agriculture was seen as a dynamic sector in medieval and postmedieval Europe, which rejected earlier theories about the countryside having a restraining effect on economic development.

There are many underlying reasons for the breakthrough of rural history in the 1950s. One factor was the increased political importance of peasants on a worldwide scale and in conjunction with colonies attaining their independence. The immediate conclusion was that peasants and rural societies were identified as essential elements of the social structure. Yet the dominant premise remained that peasant culture had filtered down to the peasants from the elite. Foster (1967) was one of several scholars to make this interpretation in a rather explicit form. Yet another conclusion gradually emerged. Redfield (1956) drew a distinction between a 'great tradition' and a 'little tradition' – between the classical, learned elite culture, and the peasant tradition – and he emphasized the existence of a mutual exchange.

The view of a conservative peasant society unwilling to accept changes that may upset traditions is similar to what is sometimes called 'the dumb peasant theory.' It implied that peasants had to be forced to develop, an assumption that largely guided Western relations with the Third World in the 1950s and 1960s, and to some extent since.

The 1970s and 1980s

From the 1970s onward, studies of peasants and rural societies became more diversified. Two partially linked phenomena began to change the picture – one was the challenge that Marxism presented to academia and the other was the success of peasant uprisings, not least in the Vietnam War. These developments challenged old thought structures, but did not lead to a new hegemony. After the major theoretical battles of the 1970s, the field was instead left open to a number of different theories.

A common question that many of the new interpretations struggled with was the relationship between agency and structure, with peasants being increasingly regarded as real actors in the historical process. One expression of this new and deeper interest in peasant studies was the creation of the *Journal of Peasant Studies* (1974–). Its editorial policy stated that the journal would be concerned with political economics and that it would attempt to understand the role of peasants worldwide, in particular outside Europe and North America.

The previous focus of anthropological research on material cultural products weakened. Instead, it was the social and cultural structure that attracted increasing attention, and this was not least evident in discussion about peasant societies. Clifford Geertz was a key figure. In the 1960s, he made important contributions to the theory on agrarian technology, and then gained even more influence with his *The Interpretations of Cultures* from 1973.

The classical study of material culture continued for some time, especially in the exchange between Eastern and Western European researchers. The Danish journal *Tools & Tillage* was established (1968–95), and for a while it was regarded as the leading international journal dealing with the development of agricultural technology in peasant societies. Of special importance as a meeting place was the Association International des Musées d'Agriculture. It was formed in 1974, formally under the jurisdiction of UNESCO. Meeting venues alternated between Eastern and Western Europe and the United States. The conference reports were published as *Acta Museorum Agriculturae* (1966–88).

There was a growing interest in rural history outside Europe, as exemplified by the publication of the multivolume *A History of Agriculture in India* in the 1980s, and the series *Science & Civilisation in China*, edited by Joseph Needham, with a remarkable volume on *Agriculture* from 1984 written by Francesca Bray.

Land reform and class conflict were intensely debated, and studies of peasant revolts and uprisings became a special genre. The geographical focus of these studies was on Europe, Asia, and Latin America, whilst studies on Africa begun early on to be more focused on the environment.

New interpretations developed in the study of long-term changes in European history as the class perspective was introduced (e.g., the Brenner debate). At the same time, there was a shift in interest from pure agrarian history to general cultural history. Here we can draw a parallel between anthropology and history, although historians had a much more recent interest in agrarian matters. By 1990, it seemed as though studies about peasants and rural society were stagnating and even decaying. However, in reality the opposite was true: rural history stood on the verge of a new leap forward.

Reorganization from the 1990s

The first wave of rural history that spanned the late nineteenth and first half of the twentieth centuries had been dominated by ethnology–anthropology, whilst the second was driven by the considerable advance of economic and social history during the 1950s and 1960s. The third wave began in the 1990s and involved different disciplines.

One such group of disciplines was social and economic history. New journals were launched: *Rural History* (1990–) in the United Kingdom; *Noticiario de Historia Agraria* (1991–), from 1998 renamed *Historia Agraria* in Spain (in Barcelona, an agrarian history journal had been published since 1983); and

Histoire et Sociétés Rurales (1994–) in France. The Royal Swedish Academy of Agriculture and Forestry (KSLA) published a series on agrarian history from 1991 onward. Higher education institutions and courses were organized in a number of countries (e.g., Austria, Belgium, Hungary, and Sweden). National multivolume syntheses were published in several European countries: in Italy during the 1980s and in 2002, in Germany during the 1990s, and in Denmark during the 1980s and in the rest of the Nordic countries (Sweden, Norway, and Finland) from 1998 to 2004. This quasi-joint Nordic endeavor came to cover, in 16 volumes, almost as many pages as *The Agrarian History of England and Wales* mentioned above. The Norwegian and the Swedish projects were also later summarized in English in two separate volumes.

The formation of three networks in economic and social history was a key development. The first, based in Belgium, was the Comparative Rural History of the North Sea Area founded in 1996 by Erik Thoen. An impressive series of books have been published, now summarized in four volumes covering northwestern Europe. The Rural History Network was formed in 2000 as part of the biannual European Social Science History Conference. The third network to be formed was the Program for the Study of European Rural Societies. It came into being in 2005 thanks to funding from the European Union's research program Cooperation in Science and Technology (COST). Hundreds of European scholars have made contacts and worked together through these networks. In 2010, the first European (and in reality international) conference for rural and agrarian historians was held in the United Kingdom and resulted in the formation of the European Rural History Organisation. The second was held in Switzerland in 2013.

Some main topics in these three networks have included property rights, the role of the state, commercialization, and food processing. Although peasant culture proper has not been extensively researched, topics such as gender and family structures have attracted much attention. Landscapes as well as agrosystems have been among other favored topics. This new rural history had new questions and answers, but largely remained in the area of research where the inclusive agrarian history had been for decades. There was, however, a shift in chronological focus from the Middle Ages to the nineteenth and twentieth centuries, which now dominates syntheses and conferences.

Medieval rural history reappeared in another context, as a parallel movement that evolved in archaeology and came to include the remnants of classical rural ethnology. There were conferences on medieval rural archaeology, and papers were subsequently published in the biannual journal *Ruralia* (1996–). Prehistorical archaeology is by definition rural, whilst antiquity is a major field of research in itself. Thus rural archaeology came from medieval archaeology. Agrarian issues had long been developing as new methods merged with new questions. New scientific methods such as pollen analysis, osteology, and dendrochronology provided answers to questions scholars had never before been able to even ask about landscapes, cultivation, and animal husbandry. Archaeological excavations at the same time moved from mounds and castles to fields and villages.

The rural archaeology conferences began with an inventory of rural settlements across Europe, and then addressed a number of different themes, often corresponding to those seen in social and economic history. Examples include marginal lands, landscapes, and even food processing (including markets and commercialization). Not surprisingly, archaeologists focused on buildings, which resulted in a direct interconnection with classical ethnology. Chronologically the focus was on the Middle Ages, although ethnological comparisons stretched right into the nineteenth century. With new excavation methods and ambitions, rural archaeology is also moving far into the modern period.

In recent decades, environmental issues have acquired an increasingly historical dimension with the recognition of long-term human impact. Journals were launched. The American *Environmental History* is the most influential. It was created in 1996 by merging two established journals: the *Environmental History Review*, founded in the 1970s, and *Forest & Conservation History*, which dated back to the 1950s. Forest history has generally tended to be included as part of environmental history research. In 1995 a European journal entitled *Environment and History* was founded. Both this journal and the aforementioned *Environmental History* have strong links with science. The issues covered have included long-term sustainability in relation to current problems such as soil erosion, salinization, and climate change.

This renewed interest in rural history did not just include the Western world, as exemplified by the formation of the Indian journal *Asian Agri-History* (1997–). Anthropology also enjoyed a renewed interest in peasant societies. An example is that Yale University in 1991 launched its Agrarian Studies Program, where James Scott was a central figure. He had already published important works about peasants in Southeast Asia in the 1970s. In 2009, he released a groundbreaking book about peasants and the state, in which he argued that many peasants actively avoided intensification of agriculture to escape taxes and control.

These movements in social and economic history, in archaeology, and in anthropology have rather few interdisciplinary contacts so far. In **Figure 1** I have tried, in a generalized way, to describe in what other major topics this research was conducted. I also tried to describe major flows of influence, though of course a web of contacts in fact existed between scholars in these different disciplines doing rural history.

A possible merger in the future could be the growing interest in continental and global syntheses. The increasing number of regional studies and syntheses from conferences and books published in English provide the material for such major projects (Rasmussen, 2010). However, new methods will be required to handle diversified and at times overwhelming information. An academic overview by Marcel Mazoyer and Laurence Roudart was published in 2006 (it first appeared in French in 1997).

Some Major Discussion

The discussion about the definition of 'peasant' meant that peasants came to be regarded as a part of a larger society. Once the crisis of the late Middle Ages was taken into account, the long waves of history came into focus. During the 1970s, research often emphasized social conflict, although it also expanded into new fields and this formed the basis for the

Figure 1 A sketch of major academic disciplines in which the subfield rural history was conducted. There are no strict relative proportions. Major flows of influence have been indicated, but a web of other contacts in reality existed between scholars in different disciplines. Sketch made by J. Myrdal and P. Thunström.

revival in the decades that followed. Yet it was the recognition of peasants' agency that most changed perspectives on a general level. The old idea of elite-dominated history was a kind of history where the majority of the people were seen as the boards of a stage on which the actors – kings and nobility – performed their play. This view has gradually been abandoned, and a fuller and richer drama appears before us.

A few constellations of themes will be mentioned, where discussions have been intense and advances considerable. One such concerns productivity, and it is rooted in the works of Slicher van Bath, Duby, and other early publications on agrarian history. Much of the later arguments are technical in nature, concerning problems of source criticism and different ways of measuring productivity.

The discussion about productivity prompts some overarching issues. One is the reconstruction of historical per capital production. Agricultural production is the single most important factor, besides demographics, prior to the industrial revolution when calculating total production. In 2005, Giovanni Federico compiled national data from the last two centuries. Now research is pushing even further back in time. If reliable data sets can be created, this will be of importance for some of the major debates. One is the ongoing debate on: Why the West? Another is the question about why and how historical expansion of production and population occurred. The Malthusian pessimistic and Boserupian optimistic views about ongoing intensification have been challenged, leading us to the next overarching issue: farming systems (Boserup, 1965).

Ideas about farming systems begin with the view that agriculture is an integrated system of interlinking elements. Scale is of importance, as we have systems from the farm level to the global level. Emphasis has often been placed on regional systems, but these must be conceptualized as subgroups when the discussion shifts to global farming systems. This change of perspective may well pose the greatest challenge to European rural history, since it is so well developed and thus has identified a number of regional systems and differences (Grigg, 1974: 152).

Another part of the farming system discussion concerns technology. The technological complex can be regarded as such, separate, and then compared and related to the social structure, or one can already from the start regard an integrated agrosystem, where social structure is inseparable from technology (Astill and Langdon, 1997; van Bavel and Thoen, 1999). As in so many discussions, the somewhat unexciting answer is that we have to do both kinds of analysis.

One problem is that research into technology was already languishing prior to the revival of rural history in the 1990s, and it has not recovered since. Tangible material will always remain essential to archeological research, and archaeology has adopted some of the earlier ethnological issues, such as buildings and construction. Classical questions about plows, harrows, and shepherding have not, however (bar some important exceptions) been intensively researched and discussed in recent decades.

The growing importance of science is another aspect of the discussion about production. Agrarian history could be an interdisciplinary field that straddles natural science and the humanities. Whilst simple facts (e.g., the nitrogen cycle) have been known for a long time, more complex ecological models are now gradually being used. An example is biologists using historical data to explain prevailing biodiversity, not only in Europe but also, for instance, in the Amazonas.

Major clusters of discussions often are like branches of an enormous tree, stretching out from a common trunk of basic themes. Discussion about themes such as property and the community is an example, where two large and interlinking branches are ownership and social conflict, whilst other

branches deal with questions about village communities and collective action. At first glance, it may seem that there are two opposing views about the relationship between different classes – one that points to conflict and tension as the essential driving force, and another that emphasizes cohesion and social symbiosis as the foundation of a society. A closer look reveals that both viewpoints often merge into a single approach, which shows that societies in which peasants (and the general public) have more influence seem to be less troubled by harsh conflict (e.g., Blickle, 2000). This change of perspective can also be seen as a shift of interest from serfs to free peasants (van Bavel and Hoyle, 2010).

A fast-growing branch of rural history is the discussion about how peasants handled common resources. An earlier, rather negative view of the village community and their common land has come to be replaced by a more positive stance. The peasant community was earlier seen as a hindrance to technological development, and it was also perceived as a threat to the environment. The idea of 'the tragedy of the commons' implied that everyone would take as much as possible from a common pool of resources. To counter this, the American political economist Elinor Ostrom and others showed that a functioning community could in fact manage common resources sustainably, and the establishment of such a community must be regarded as a historical process (Ostrom, 1990; De Moor et al., 2002). This not only had an impact on the environmental discussion but also prompted renewed research into village communities.

Another constellation of themes and discussions concerns the market. The peasant-farmer discussion is obviously rooted in this, yet the market was now no longer seen as alien or even hostile to a peasantry striving for self-sufficiency. Instead, the market came to be seen as a driving force and even a primary goal for production in rural societies. This links in with the aforementioned discussion about farming systems and productivity. Several important case studies have been produced, including Bruce Campbell's research on medieval London (Campbell et al., 1993). This also feeds into other key discussions conducted in recent decades. If peasants, who made up the bulk of the population, had goals other than just producing food for themselves, for instance if they strived for 'gadgets,' this could incite them to work harder. This is connected with the theory of the 'industrious revolution' (De Vries, 2008).

There are of course numerous other major discussion threads, such as gender. This has been very much steered into a discussion about marriage patterns and the division of labor, on both European and global levels (as is true of all discussions mentioned here). Environmental issues could also be examined in more detail, not least with respect to climate change. The antiquity has hardly been mentioned, though research has been very successful, highlighting subjects like water management and grain trade. The most important subject not given its space is probably global farming systems. Research is making great strides in exploring the agrarian and rural histories of Asia, Africa, and the Americas. The next leap forward will certainly be based on this new knowledge base.

The overarching themes mentioned here – the property and community, the market and commercialization, and productivity and farming systems – have one common denominator: They all basically regard peasants as actors in their own right. In coming decades, it can be expected that this will be counterbalanced by growing global research, which will show large systems and path dependency within these systems. Rural history will be more globally interconnected because scholars now are publishing material in a common language: English. Historical knowledge about land use will presumably be much in demand, as such knowledge is of great use in helping to solve such global problems as climate change. One interesting question is, then, how this grand-system approach will work with the peasant-actor approach that has become so strong in rural history over recent decades.

This article is a revision of the previous edition article by M. Kearney, volume 16, pp. 11169–11171, © 2001, Elsevier Ltd.

Abstract

Peasants, an anthropological approach, begins with Kroeber's definition of them as part societies and part cultures, describing a segment of national societies as a class of people who are family-based agriculturalists who produce food for themselves and for the market. They also provide (under various forms of coercion) labor, rent, taxes, and manpower for armies or pharaonic constructions such as temples, roads, or dams. Their culture is folk based but related in interesting ways to high-cultured learning practiced by elites. Politically, peasants are often subjects of landowners and even in free communities, they are subservient to the dictates of members of the state and to ecclesiastical control. Regularly exploited and overworked, they occasionally rise in rebellion and participate in revolutionary wars, but more frequently resist exactions in devious ways, driven by attempts at self-defense that appeals to an ethic, named by James C. Scott, the moral economy of the peasant. It asserts the higher moral right to food and shelter and to family social relationships in the face of constant expropriation of their crops, labor, animals, and land. Increases in land productivity are achieved through labor-intensive ways and environmental management seeking sustainability as a way of life rather than the single-minded pursuit of profit. Their participation in markets as traders and sellers of labor and crops is an important aspect of their life, even though part of their production is consumed directly. In modern times, peasants, in alliance with other political actors, resist changes in agricultural technologies such as mechanization, chemical fertilizers and pesticides, genetically modified crops, and the extraction of mineral or oil resources that adversely affect them. Peasants also extend their lifestyles to urban areas where, as casual labor migrants, they re-create zones of peasant life reminiscent of their rural home base, even if they now travel to other countries to find work and send money back to sustain the peasant base.

Peasants are primarily rural dwellers who, with their traditions, labor, tools, and land, produce food for themselves and for nonfarm populations. Although they are contained within the boundaries of countries, their cultural patterns are set apart and therefore aptly defined by Alfred Kroeber (1948) as "part societies and part cultures." In common English, the word peasant also carries an offensive overtone referring to an uncouth person, ill mannered and uneducated, an opinion originally held by the mannered aristocrats of renaissance times in Europe. Other, more positive and romantic, meanings have been added and these have shifted over time. Intellectuals like the Brothers Grimm the German folklorists, Vincent van Gogh the Dutch painter, Nicolai Rimski Korsakoff the Russian musician, or Amalia Hernández the Mexican ballet choreographer found sources for inspiration in portraying aspects of peasant life with admiration that enhanced the identity of their nations.

In Europe, the musings of Karl Marx, Friedrich Engels, and Vladimir Lenin on the defeudalizing process brought about by the bourgeois revolution and the role played in it by the peasantry have always provided a source of inspiration for peasant studies (Marx, 1971; Lenin, 1982). Theodor Shanin's (1973, 1971) *The Awkward Class* and *Peasants and Peasant Societies* on the East European peasantry are important references for its complete treatment of serfs and independent peasants that bolster Immanuel Wallerstein's (1974) general point that it is in the semiperipheries of the world capitalist system, like Eastern Europe, where in agricultural estates or in small villages, a subordinate class of peasants were the food producers, the tax and tribute payers, and the suppliers of soldiers.

Peasant Cultures

Sociocultural anthropologists doing field work in Europe concentrated their work in marginal regions of Europe such as Italy (Banfield, 1958), Ireland (Arensberg and Kimball, 1968), Greece (Peristiany, 1966), or Spain (Pitt-Rivers, 1966; Kenny, 1962) looking for particular regional cultural patterns such as aspects of envy, honor, and shame or forms of self-government and lack of cooperation because they felt peasant cultures there had remained more ingrained than elsewhere in that continent.

Latin America, particularly Mexico and the Andes where the Aztec and Inca civilizations had established a stable tribute paying agricultural peasantry that the Spanish empire took over and transformed, is another Wallersteinian semiperiphery. Anthropologists specialized in community studies where the emphasis was strongly cultural and local, in that, Mexican peasant culture and personal character traits seemed to form distinct patterns worthy of note. Much of this work was inspired by the pioneering work of Robert Redfield (1973) whose description of a 'folk society' in Tepotzlán revealed the positive value systems he thought were at the heart of the peasant ethos. Oscar Lewis (1963) restudied the village and found much that was negative and nasty, raising the question whether anthropologists find in the field that which they are looking for. With the 'folk urban continuum' Redfield (1956) developed from field work in the village of Chan Kom, Yucatan, a mixed Maya and Spanish language population practicing a syncretic religion that blended Catholicism with Mayan beliefs, he pointed out how this folk society was neither tribal, nor urban, but in between, sharing characteristics of both and yet unique and whole. He also

showed how cultural patterns derived from dominant urban centers of power, learning, and cultural production of mostly Hispanic (the 'big tradition') tended to be whittled down and be reinterpreted to make them compatible with the villager's oral folk practices (of the 'little traditions'). This generalization is applicable to other stratified cultural contexts such as India or China.

Eric Wolf and Sydney Mintz (1955) outlined the conditions under which rural proletarians who worked in capitalist plantation systems were distinguishable from traditional rural estates (*haciendas*) with peasant serfs bound to the landlords through other forms than wages. Elsewhere 'free' peasants were of two types, 'closed corporate communities' (Wolf, 1955) with collective land holdings and civil religious self-managed local authorities were the result of the colonial policies of indigenous reservations, ecclesiastic control, and taxation, contrasted with the more 'open' market oriented and mestizo colonizers of peripheral areas as producers of mixed subsistence and exportable cash crops, such as coffee production in Venezuela (Roseberry, 1983) or even on the banks of the Amazon river in Brazil (Harris, 2000). Wolf's short textbook *Peasants* (1966) summarized extensive scholarship and is widely used by scholars because he wrote with clarity and a perspective of a peasantry as a type that is an integral part of the world.

Peasant Politics

The fact that Mexican peasants had participated extensively in the 1910 Mexican Revolution that culminated in an agrarian reform that created modern collective land holding units for them (*ejidos*) and that the ruling party relied on the support of peasants (*campesinos*) adds a necessary political component to the conceptualization of peasants in social sciences. Beyond liberating themselves from landlords, peasants have developed complicated relationships with national states. In Latin America, peasant rebellions, peasant movements, and oppositional stances are extensively covered in the literature by scholars and protagonists (Landsberger, 1969; Handelman, 1975; Zamosc et al., 1997; Blanco, 1972; Marcos, 1995; Menchú, 1964).

James C. Scott working in Malaysia, outlining the *Moral Economy of the Peasant* (1976) described how a collective ethos of the right to subsistence, and its defense against its encroachment, underwrites the political stances peasants will take when confronting exploitative landlords, traders, or members of the state. Not always violent and only partially effective, as he points out in *Weapons of the Weak* (1985). Resistance has underscored the complex confrontational aspects as a characteristic practice of peasant politics in the defense of their modes of livelihood. Indeed, rather than allies, Bernstein (1994) characterizes the peasants as victims of rapacious states reminding us of murderous land collectivization of the Soviet and Chinese regimes, repression campaigns in Central America, Southeast Asia, or India. The state against the peasants also manifests itself in less strong terms, as cooperativization schemes in Peru (Mayer, 2009) even in supposedly benevolently intended development programs (Escobar, 1995) but nonetheless imposed and counterproductive. One can observe most recently, peasant resistance against multinational companies whose extractive industries like mining, oil, logging, and other environmentally damaging resource extractions are opposed by affected populations (Bebbington, 2011). In the changed politics of these times, these movements often clothe themselves in ethnic terms as Indigenous rather than as peasants, although they are both. Wolf's *Peasant Wars of the Twentieth Century* (1973) goes beyond resistance, because he studied active peasant participation in the Mexican, Russian, Chinese, Vietnamese, Algerian, and Cuban revolutions, and in *Europe and the People without History* (1982) used Marxism to point to the expansion of capitalism that generated the peasantries of the world, while at the same time ignoring their historical role in this narrative.

Peasant Farm Ecology

Clifford Geertz (1963) using ecological approaches described how peasant agricultural intensification in Javanese irrigated rice terraces *sawa* 'involuted' as increasing population and rising taxation requirements squeezed ever more products out of their environmentally amazingly well-managed agroecosystems. Family-based labor-intensive agricultural systems produce surpluses and generate inward-looking self-managed culturally distinct ecological arrangements controlled by village governance such as the Mexican maize *milpa* (Alcorn, 1984), the Andean maize and potato *chacras* (Brush, 2004), or the Swiss Alpine dairy systems (Netting, 1981, 1993). In all of them, it is the autonomous family farm that is part of a collectively self-governing village that often holds parts of the land collectively and manages a 'commons' (Ostrom, 1990) that guarantees production, manages the internal politics, and ensures sustainability.

The farming family peasant household has certain characteristics that differ in degree from what is a basic assumption in economics. Because there is no separation between the resource-holding household and the income-producing household, the efficiency models of the single-minded profit-seeking small firm in economic theory does not fully apply to peasant households. Given that the prime responsibility is to provision family members, the needs of the household often loom larger than the profit-seeking objective. Moreover, as Stephen Gudeman points out in *Conversations in Colombia*, material flows of labor expenditures and harvested farm products flowing over time through the peasant farm ecosystem allow it to become more diversified, to grow in biomass, and increase in members' well-being without any clear cutoff point: "The house model has no goal or end, it is a mode of life, a set of practices" (Gudeman and Rivera, 1990: p. 116). An Indigenous formulation with Quechua and Aymara concepts of similar subsistence-oriented ideas has recently been enshrined as the *buen vivir* goal in the constitutions of Bolivia and Ecuador (Gudynas, 2011).

Western technological revolutions in agriculture, many of them associated with capitalist agriculture and multinational corporations, although responsible for vastly increased output, nonetheless have negative consequences for peasants who have been displaced, expropriated, marginalized, proletarianized, injured, or starved in various regions of the world.

The process of expropriation to make room for modern agriculture is often violent and legal redress slow or absent, creating a political dimension to this process. Mechanization comes with consolidation of land holdings, provoking land invasions and calls for agrarian reforms. Chemical fertilizers and pesticides bring with it soil and environmental degradation, pollution, and illnesses, raising the call for regulation and protection as well as the implementation of more environmentally benign forms of production. The plant genetic revolution for high-yielding varieties and genetically modified seeds of food crops causes the loss of biodiversity with it fears of future unintended, uncontrollable biological phenomena. It also concentrates ownership over the seeds in the hands of private multinational corporations, raising ethical and practical concerns about who owns seeds and whether they can be commoditized. Concentration of food-processing and distribution networks kills small businesses on which peasants rely. Industrialization of foodways has consequences for the health of the people it feeds.

In many parts of the world, peasants and their allies are resisting these trends in various ways, by forming new social movements, joining the environmentalists and consumers, appealing to international organizations for rights and protection, and inventing alternatives. Examples are the international alliance of organizations *Via Campesina* (peasants way) and the *Slow Food* movement which defend peasant production and processing strategies. *Via Campesina* states in its brochure that "small farmers, including peasant fisher-folk, pastoralists and indigenous people, who make up almost half the world's people, are capable of producing food for their communities and feeding the world in a sustainable and healthy way" (http://www.viacampesina.org).

The Dutch anthropologist Jan Doeve van der Ploeg (2008) studied several instances of 'repeasantization' around the globe describing ways in which people are readopting some of the 'peasant principles' to resist against the forms that agribusinesses have been developing. Repeasantization fights against the depredation of uncontrolled free enterprise as embodied in the neoliberal concept of the commodity-specialized profit-seeking commercial firms who accumulate profits. Many of the strategies are derived in interesting ways from classic peasant cultural, social, political, and environmental strategies adapted to modern contexts.

Peasant Economics

Not pursuing the profit motive in the way that an enterprise would, does not mean, as Mayer and Glave (Mayer and Glave, 1999) have shown, that peasant households do not seek to gain money from market transactions. When not required for farm work, a favorite activity is to engage as traders in peasant marketplaces to make money as *Penny Capitalists* (Tax, 1963). Mayer's *Articulated Peasant* (2002, 2005) shows that households are nodal points in extensive networks of reciprocal, barter, and cash transactions that extend outward from the village and region to capital cities within their countries, and since the 1980s, beyond Peru.

Off-farm peasant rural labor power concentrates in centers of casual employment, principally cities and extractive industries to supplement the farm base. The economist Alain de Janvri (1981) in *The Agrarian Question and Reformism in Latin America* calls this characteristic 'functional dualism' of Latin American peasantries in that it operates a subsistence farming sector and it is an active participant in the market, selling labor, handicrafts, trading, building, and investing. It is functional because the costs of creating the labor force and its partial maintenance are not borne by the employer but by the peasant/laborer. When this labor is urban based, it creates a dynamic that Bryan Roberts (1978) calls cities of peasants. Many aspects of peasant ways of life, such as foodways, cultural institutions, kinship patterns (Lobo, 1982), forms of mutual aid, reciprocity patterns (Lomnitz, 1977), and marketing strategies (Seligmann, 2004; Clark, 1994) are re-created in cities. Scholars like Alejandro Portes et al. (1989), Marie Estelie Smith (1989), and Hernando de Soto (1989) have labeled it the 'informal economy' and point out that informality is very dynamic and pervades ever larger in sectors of city neighborhoods, segments of the economy, and financial markets. The informal economy is an outgrowth of the peasant economy.

International labor migration without completely cutting ties to the rural home base entails, as Michael Kearney (1996) so nicely argues in *Reconceptualizing the Peasantry*, a triple cultural transformation. The *Mixe* Indian from the highlands of Oaxaca becomes a generic poor Mexican on reaching Tijuana on the United States–Mexican Border, and once crossed to the other side becomes a *Chicano* able to manage multilingual multicultural situations, a member of an underclass and an illegal who nonetheless works, lives, and saves, and, occasionally, even thrives. When he does so, he sends money back home. In 2007, remittances sent back home by migrating Latin Americans amounted to US $66.5 billion in more than 100 million small international transactions by about 10 million people (García Zamora and Orozco, 2009). That amount of money exceeds foreign investment and international development aid in many countries and, therefore, has become of crucial importance in the management of the flow of currencies, their national economies, and financial operations.

Therefore, contrary to previously held commonplaces, peasant societies are an intricate component of today's capitalisms and not a disappearing social segment that is held to be tradition bound that will not modernize according to the designs of the current neoliberal ideology (Brycerson et al., 2000).

Peer Review and Quality Control

Silvio O Funtowicz, Centre for the Study of the Sciences and the Humanities (SVT), University of Bergen, Bergen, Norway
Jerome R Ravetz, Institute for Science, Innovation and Society, University of Oxford, Oxford, UK

Abstract

Peer review is the recognized standard for quality control in science. There is a growing awareness about the need to introduce modifications to the traditional peer review process in order to meet the challenges of a continuously expanding scientific enterprise, the emergence of new forms of science, and the impact of new technologies. The growing application of science and science-based technologies to society requires innovative quality control mechanisms and the inclusion of new stakeholders. Collegial peer review is being rapidly transformed to review by an 'extended peer community,' raising important issues to the governance of science.

Background

Peer review is a mechanism for quality control in science, including the assessment of proposed projects and of completed work. Its roots go back to the emerging science of seventeenth century, when novelty in natural knowledge became distinguished from technical invention, and the ideals of reproducibility and publicity became established. Peer review was acknowledged by the mid-twentieth century as the unquestioned norm in academic science.

Recent experience has shown the need for important modifications in the process of quality assurance, such as changes to the traditional, largely informal, procedures of collegial peer review, in order to take into account the emergence of new forms of science, the increased competitiveness of the research enterprise, the impact of new technologies, and the inclusion of new stakeholders. Collegial peer review is being rapidly transformed to review by an 'extended peer community.'

Among contemporary forms of scientific practice, curiosity-driven research with no regard for applications has been increasingly marginalized. A diversification has occurred so that quality assurance must also be considered in such areas as mission-oriented and issue-driven research, technoscience and innovation research, and the provision of scientific advice for policy.

As the unquestioned norm in academic science, it was assumed that quality was unproblematic, owing to some special ethical disposition of scientists and their methods. With subsequent transformations in the social practice, embeddedness, and pervasiveness of science in society – which now extends into the economy, technology, policy, and life forms and styles – corresponding changes in quality assurance, are urgently needed. The crucial requirement is for a more aware understanding of the encompassing community of those producing, evaluating, sharing, profiting from, and even 'suffering' the products and processes of science (see, e.g., Stampa, 1997).

In most other spheres of institutional activity, the formalization of quality assurance has become the norm, as, for example, through the wide-ranging standard-setting procedures of the International Standards Organization. In academic science, however, along with cultural pursuits like the arts, the methods have been and are, still, largely informal. Science has been almost unique in having self-assessment performed by accredited practitioners rather than by users or external critics. To what extent and in what ways this must change to keep pace with science's expanding role in public and private life has become an urgent question in the conduct of science, in the governance of research and in the coevolution of science and society.

The assurance of quality is not a straightforward task. This has been known since the time of the Romans, as indicated by the Latin motto *quis custodiet ipsos custodes?* (Who will guard the guardians themselves?). This motto implies an indefinite iteration. It is a reminder that, however, routine may be the tasks of quality control, full quality assurance demands yet higher levels of supervision at which informality, extended participation, and explicit value judgments are necessary (Funtowicz and Ravetz, 1990).

These insights were introduced in industrial quality control by the pioneering work by William Edwards Deming at the end of the 1940s. His concepts of profound knowledge and total quality assurance were successfully applied by Japanese car manufacturers before being imported back, much later, to the US. Edwards Deming's ideas were quite easily absorbed in the Japanese cultural landscape. These ideas included the establishment of quality circles, in which the assembly line was transformed into a kind of participatory process. Two aspects of this process were quite revolutionary: the first was the extension of the community of quality controllers and evaluators to the work force, relying on practical knowledge, experience, and commitment; the second was the encouragement of whistle blowing, whereby any member of the community, including the work force, was entitled to stop the process if they believed that quality was violated. On Edwards Deming's philosophy of quality, see *Out of the Crisis* (Deming, 1986).

As long as science remained mainly academic, problems of quality were assumed to be resolved by self-correction, anticipating or responding to peer criticism; a process conceived as part of the very nature of the scientific endeavor. The informal systems of checking by peers seemed a rational and efficient response to the problem, rather than a culturally contingent mechanism characteristic of a particular epoch. Scientific facts

 http://dx.doi.org/10.1016/B978-0-08-097086-8.85016-3

were believed to be discovered by a reliable method, and scientists themselves were viewed as being endowed with certain superior moral qualities that protected them and their work from ordinary human failure or error. This self-correcting property of science could be explained in sociological terms, as in the four norms of scientific institutional practice expounded by Robert K. Merton in 1942 (Merton, 1973[1942]): Communalism, Universalism, Disinterestedness, and Organized Scepticism defined the ethos of modern science. Philosophically, it could be justified in the committed, determined attempts at self-refutation supposed by Karl Popper to be normal scientific practice (Popper, 1959), where the refutation potential becomes the hallmark of a scientific hypothesis.

Science as the Endless Frontier

With the onset of the industrialization of science after World War II, the self-conscious study of science as a social activity, including the methods of quality assurance, became inevitable. With the adoption of Vannevar Bush's report, Science the Endless Frontier (Bush, 1945), the stakes of the scientific enterprise became higher, inviting scrutiny of the quality of processes and products. Growth in size, capital investment, scale, and social differentiation within science created divisions between managers and research workers, as well as between researchers and teachers in universities. A *Gemeinschaft* (community) of scholars could no longer realistically be assumed. The earliest disciplined analyses of the quality of production in science were quantitative. Derek J. de Solla Price, who devised some measures of quality and provided analyses of its distribution, did the pioneering work. He noticed that at the leading British science reference library, only a minority of journals was ever requested. The contents of the others could be inferred to have no interest, and hence to be of very low scientific quality (Price de Solla, 1963). This phenomenon is a reminder that 'quality' is a relational attribute, and its definition 'fitness for purpose or function' depends on whose purposes are dominant; not always perhaps those of a community devoted to the advancement of learning and achievement of reliable knowledge, but possibly only of those scientists working under constraints of 'publish or perish.'

Price's studies were continued in two directions. At the Institute for Scientific Information, Eugene Garfield produced more searching and sophisticated measures of quality, using citations rather than mere number of publications. Such attempts at quantification were bound to become controversial (Brooks, 1982; Garfield, 1970, 1972). It was impossible to avoid bias in the selection of the relatively small set of journals used for citations; those in conventional mainstream English-language research science were inevitably privileged at the expense of all others. Further, when quantitative measures of citations came to be used as indicators of academic merit, manipulative practices, including reciprocal citations, inevitably developed. The deep problems of a quantitative proxy for quality suddenly became acute.

In a more reflective vein, Jerome R. Ravetz applied the *quis custodiet* principle to analyze the vulnerability of the quality assurance system in science. He observed that the processes of peer review are conducted largely informally and (unlike research) are not themselves normally submitted to open scrutiny and review. They require different competences, which are not part of the formal training of scientists; and they also are more open to a variety of abuses, ranging from bias to plagiarism. One can understand in these terms the phenomena of low quality, both in scientific research and in technological development. Thus, while denying that the practice of science automatically produces a higher morality, Ravetz agrees that moral standards are necessary for the successful practice of science. On this basis, he stresses the importance of morale and morality (and ultimately idealism and leadership) in science (Ravetz, 1996[1971]).

This analysis offers a background for the increasing interest in trust as an essential element of practice in science, in society, and in their interactions. The broader society has provided resources to the esoteric activities of science because it trusts the scientific community to make good use of them. There has always been an undercurrent of distrust, based on evidence either of pointless research or of malign applications. Once science became deeply involved in technology and related policy problems that crucially affect public health and welfare, the traditional relations of trust could no longer be assumed. It appeared to be necessary for the principles and practices of accountability to be extended from the institutions of political and economic governance (as, e.g., representative democracy) to those institutions that govern science and its applications.

Quality control in research science has become more difficult as the relatively inflexible technical requirements of the traditional printing process have first been relaxed, and then made obsolete by novel information and communication technologies and economic restructuring. There no longer is a well-defined gateway to publication through the institutions that control reproduction of, and hence access to, documents. First through inexpensive photocopying and now through the Internet, it has become easy for anyone to distribute knowledge wares to an unrestricted audience. It is like a reenactment of the period that followed the invention of the printing press and the publication of Gutenberg's Bible around 1450. Now, as then, the monopoly of knowledge dissemination is collapsing and new and expanded interested audiences are being created.

In addition, the presence of the global media tends to bypass the traditional processes of evaluation that were conducted personally among colleagues. The demystification of scientific practice enables such events to become news, and, at the same time, is fostered by their being exposed. Top scientists become like media celebrities – needing the media for advertising themselves yet simultaneously hating them for their unwanted intrusions.

Isolated scientific results can and have become media events (Close, 1991). Seralini and colleagues' rat study, relating cancer to genetically modified maize published in a peer-reviewed journal (Seralini et al., 2012), created not only great controversy among scientists (Butler, 2012) and stakeholders (see, for example, http://www.euractiv.com/innovation-enterprise/commission-science-supremo-endor-news-514072), but a new form of science-related reality TV show as Russian scientists planned to reproduce and broadcast the genetically modified organism (GMO) experiment. The scientist in charge of the project told the news agency: "This is a unique

experiment …. There hasn't been anything like this before – open, public research by opponents and supporters of GMO" (RT.com, 2012).

All those with an interest in the outcome, such as researchers, consumers, politicians, regulators, and the stock market, become potential stakeholders in the evaluation and promotion of the results. Thus, science arguably becomes accountable to a drastically extended peer community in the quality assurance process. The criteria of quality applied by these heterogeneous actors need not be identical to those of public knowledge generated within the tightly knit scientific networks of academic science.

Pathologies of Science in Society

These developments may be judged in different ways. While they may seriously disrupt the procedures of quality assurance in normal science, they can also bring needed public scrutiny to bear on innovation, controversies and, even, scandals. In 1999, the Netherlands Environmental Assessment Agency was accused by an employee, senior statistician Hans de Kwaadsteniet, of lying and deceiving; his claim was that figures released by the agency, based on virtual reality computer models were essentially unreliable. The whole episode, which lasted several months, ended with the transformation from a technocratic model of quality assurance to a more accountable, transparent, and participatory paradigm (Petersen et al., 2011).

The 'Baltimore affair,' centering on the US Nobel laureate David Baltimore's laboratory at MIT, was perhaps in its time the most notorious case in which a dispute about scientific misconduct was blown up into a lengthy, visible, political saga that unquestionably damaged all the individuals and institutions involved (Kevles, 1998). The episode was symptomatic of an increasingly recognized problem of 'deviance' in science, which carries the unspoken danger that, without timely correctives, misconduct might become the norm.

There has been a growing awareness and concern, expressed in studies and articles not only in the scientific press (Jha, 2012; Zimmer, 2012), about the quantity and quality of fraud and misconduct cases (Fanelli, 2009; Corbin, 2012). Several initiatives have been proposed to tackle misconduct and related issues, such as retractions (see, for example http://retractionwatch.wordpress.com) and the reproducibility (see, for example, http://www.reproducibilityinitiative.org) of research results (Nature Biotechnology, 2012). The problem does not affect a single discipline but it is felt across a wide range of research areas; thus, for example, the Nobel Laureate Daniel Kahneman, has challenged psychologists to "clean up their act," according to Nature (Yong, 2012).

All these developments affect the maintenance of trust, which is necessary for ordinary scientific practice and even more so for quality assurance. As in other professional domains, the normal tendency in science has been for misconduct to be covered up by the responsible institution (not necessarily by the community of scientists). In such situations, ultimate exposure does even more damage and further erodes the basis for mutual trust. Grigory Perelman, perhaps the most gifted mathematician of his generation, is quoted to have said, after refusing the European Mathematical Society top prize in 2007 that the award committee was unqualified to assess his work (Paulos, 2010). Perelman's mistrust toward his colleagues and the organized mathematical community is also illustrated by his decision to publish his proofs of the geometrization conjecture in the nonpeer reviewed archive for electronic preprints, arXiv. Nasar and Gruber report that Perelman had not mentioned the proof or shown it to anyone. "I didn't have any friends with whom I could discuss this," he said in St. Petersburg. "I didn't want to discuss my work with someone I didn't trust" (Nasar and Gruber, 2006).

Attempts to circumvent the need for trust by increasing bureaucratic surveillance are likely to be counterproductive in their own way, by erecting impediments to free inquiry and communication among colleagues.

The relations between social science and natural science have also been transformed during the last decades, with implications for quality control. Starting with the acceptance of natural science as the ideal of knowledge, essentially independent of social forces, there has been a gradual but accelerating shift toward recognizing all sciences as incorporating social constraints and biases. An early critical interaction was in connection with the astronomical community's management of the eccentric Velikovsky (De Grazia, 1966). Later, the social science community embraced Thomas Kuhn's disenchanted picture of 'normal science' (Kuhn, 1970). Finally, post-Feyerabend studies of science reexamined the whole institution of scientific inquiry without presupposing any privileged status in relation to either virtue or natural knowledge (Bloor, 1991; Barnes et al., 1995; Collins and Pinch, 1993; Fuller, 1993).

When natural scientists, led by physicists, eventually confronted the emerging socialized picture of their discipline, the reaction was so strident that 'science wars' became an appropriate label (Gross et al., 1997; Nelkin, 1996; Ross, 1996). Sociologists of science and postmodernists were indiscriminately blamed for all the ills of science, including decline of public trust, budget cuts, resurgent Creationism, and even poor teaching of science. A physicist whose hoax article (Sokal, 1996) was accepted by a leading cultural studies journal, *Social Text*, helped to crystallize the attack (Bricmont and Sokal, 1998). The implication was that the critics of science had no real quality control of their productions. The science warriors' assumption was that within real science, such problems are prevented from occurring because of the verifiable empirical content of scientific research. In the ensuing debate, there was little mention of the ease of publication of erroneous or vacuous research in the standard scientific literature. Historical episodes, like Millikan's manipulation of his oil-drop results in the course of a controversy on the charge of the electron, were discounted as mere embarrassments (Segerstale, 1995).

It has been presupposed thus far that 'science' refers primarily to traditional basic research. However, among contemporary forms of scientific practice, curiosity-driven research with no regard for applications is giving way to new forms of science. Quality assurance must also be considered and performed in such areas as mission-oriented, issue-driven and innovation research, forensic science (Foster and Huber, 1997; Jasanoff, 1995), and the provision of scientific advice for policy (Jasanoff, 1990; Salter, 1988). In addition, the products themselves and the media through which they are diffused increasingly are diversified. For example, patents

are now a common outcome of a research process, and this form of intellectual property is radically different from traditional published papers (Myers, 1995). Also, results are reported in nonpeer reviewed electronic Web sites, unpublished consultancy reports and gray literature, or kept confidential within institutions or even totally sealed under lawyer–client confidentiality and legal settlement agreements.

Peer Review Extended and Democratized

With traditional peer review as the norm, the challenges of quality assurance for these new products and processes are nearly unrecognizable. A genre of critical literature has developed, with some authors directing anger at the new contexts of scientific production (Huber, 1991), and others more clearly appreciating the problems they present (Crossen, 1994; Jasanoff, 1990, 1995).

A parallel diversification has occurred in the types of knowledge production that are accepted as legitimate. The democratization of knowledge now extends beyond the juries who assess the quality of technical evidence in courts (Jasanoff, 1998) to include those who master previously esoteric aspects of their predicament (e.g., illness, contamination, pollution, oppression, discrimination, exploitation) through special-interest groups or Internet-based social media. In addition, claims of specialized or local knowledge are present in even more diverse contexts, as among indigenous peoples, and in systems of complementary or 'traditional' medicine. These claims are commanding increasing commercial and political support among various publics, as well as gaining explicit recognition in numerous international treaty regimes. As a result, a new philosophy of knowledge appears to be emerging, based on a new disciplined awareness of complexity, in which a plurality of legitimate perspectives is taken for granted (Funtowicz and Ravetz, 1992). Modern science, with its characteristic methodology and social location, is part of this enriched whole, but not coextensive with it. The criteria and tasks of quality assurance must explicitly involve additional values and interests, incorporating even the ontological commitments of groups other than scientists. This new configuration has been termed postnormal science.

There are now many initiatives, increasing in number and significance all the time, for involving wider circles of people in science, decision making and implementation on policy issues. The contribution of all the stakeholders in cases of postnormal science is not merely a matter of broader democratic participation. Novel and emerging technoscientific issues, promoted and produced as innovation research, are in many ways different from those of traditional research science, professional practice, or industrial development. Each of those has its established means for quality assurance of the products of the work, whether through peer review, professional associations, or the market. However, for these new forms of knowledge production, the maintenance of quality depends on open dialogue between all those affected. In postnormal science, it is called an 'extended peer community,' consisting not merely of persons with some form or other of institutional accreditation, but rather of all those with a desire to participate in the resolution of the issue. Since this context of science involves politics and policy, we might see this extension of peer communities as analogous to earlier extensions of the franchise in other fields, such as women's suffrage and patients' rights.

Extended peer communities are already being created, in increasing numbers, either when the authorities cannot see a way forward, or when they know that without a broad base of consensus, no policy can succeed. They are called citizens' juries, focus groups, consensus conferences, or any one of a great variety of other names; and their forms and powers are correspondingly varied. But they all have one important element in common: they assess the quality of policy proposals, including a scientific element, on the basis of the science they master combined with their commitment and the knowledge of the ways of the world. In addition, their verdicts all have some degree of moral force and hence political influence.

These extended peer communities will not necessarily be passive recipients of the materials provided by experts. They will also possess, or create, their own 'extended facts.' These may include craft wisdom and community knowledge of places and their histories, as well as anecdotal evidence, neighborhood surveys, investigative journalism, and leaked documents. Such extended peer communities have achieved enormous new scope and power through the Internet. Activists scattered among large cities or rain forests can engage in mutual learning and coordinated activity, providing themselves with the means of engagement with global vested interests on less unequal terms than previously. Along with the regulatory, evaluative function of extended peer communities, another, even more intimately involved in the policy process, is springing up. Particularly at the local level, the discovery is being made, again and again, that people not only care about their own environment and health but can also become quite ingenious and creative in finding practical, mixed social, and technological means for its improvement; and local people can imagine solutions and reformulate problems in ways that the accredited experts, with the best will in the world, do not find 'normal.' This is most important in the phases of policy formation, and also in the implementation and monitoring of policies. Thus in addition to extending the traditional processes of quality assessment, participants can enhance the quality of the problem-solving processes themselves.

Thanks in large part to the new powers created by information and communication technologies and the new social media, the extended peer community can on occasion inject itself into quality debates of a traditional sort. A notable instance of this tendency is the activity of the so-called deniers in the debate on global warming science. Some have focused on the evidence adduced for the phenomenon of global warming, independently of whether it is actually happening. The most famous of these is Steve McIntyre, a retired mining engineer, who has criticized the tree-ring analysis conducted by Michael Mann and others. Part of his criticism was about the persistent refusal of Mann to supply him with his data, which were obtained on public funds and so would be presumed to be in the public domain. His more serious criticism related to the statistical techniques underlying the 'hockey stick' picture of global temperatures in recent centuries. Although his arguments were never formally recognized by the academic scientists he criticized, he did gain important respect from key science journalists (Harrabin, 2011). McIntyre has his own site

in the 'blogosphere,' but he and others became a powerful presence through popular Web sites like "Watts Up With That?" (http://www.wattsupwiththat.com, accessed 10.09.13.), which have attracted millions of visits and also won prizes for quality. In this way, the new social media have given strength to the extended peer community in science in a way reminiscent of the contribution of printing to the Reformation.

Quality assurance, thus, can be seen as a core commitment of postnormal science, replacing 'truth' as science's ultimate regulative principle (Funtowicz and Ravetz, 1993). Defined in terms of uncertainties and decision stakes, quality assurance encompasses public interest, citizen, and vernacular sciences. In a period of domination by globalized corporate science (Gibbons et al., 1994), this effort to make scientists accountable to interested groups presents a coherent conceptual alternative for the survival of the public knowledge tradition of science. Collegial peer review is thereby transformed into review by an extended peer community. This new form of quality assurance will be given its institutional structure and routines by those heterogeneous actors who put it into practice.

Peer Review: Organized Skepticism

Katri Huutoniemi, Helsinki, Finland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article approaches the evolution of peer review from a social scientific perspective, and looks at the various modes of the practice as instantiations of the norm of organized skepticism. Coined by Merton, organized skepticism is both the methodological and institutional mandate for scientific knowledge production: it guarantees good quality while preserving the social contract between science and society. Recent institutional changes in knowledge production and evaluation, however, imply an increasing ambiguity in the purposes and beneficiaries of peer review, and raise a question of whether and how it still grants intellectual authority.

Introduction

Science produces knowledge that is based on evidence, and it is thought to work best in conditions of unrestrained scrutiny. Epistemic scrutiny is, indeed, regarded as one of the glories of science as a systematic pursuit of knowledge. Peer review is the most wide-ranging institutional mechanism for realizing this scrutiny. Peer review is in some sense the *sine qua non* of the academy, but there exists little research on its historical development within the social and behavioral sciences, specifically. However, it appears that peer review developed in this field in ways very similar to how it developed in natural sciences and medicine, even if the origins of peer review can be traced earlier than the institutionalization of social science disciplines themselves.

I approach the question of peer review in historical and social scientific terms, and address questions raised about peer review by social scientists. I begin in the most obvious place, with Robert Merton's norm of organized skepticism, and look at the evolution of peer review through that lens. By drawing on existing historical accounts (e.g., Abbott, 1999; Biagioli, 2002; Burnham, 1990; Kronick, 1990; Rennie, 2003; Spier, 2002), I sketch out how the different modes and practices of peer review have (or have not) exhibited this ideal. I then discuss the changing contexts of peer review, which imply an increasing ambiguity in the purposes and beneficiaries of the practice. Today the social mechanisms that authorize and channel peer review are shaped as much by considerations of public policy as by the technical criteria of the scientific community (Chubin and Hackett, 1990). In conclusion, I identify some unresolved questions about peer review, among them the validity of the norm of organized skepticism itself. Throughout the article, I touch upon key conceptual issues, including the definition and scope of 'peer,' the range of peer review from *ex post* to *ex ante* forms, the tension between anonymity and openness, as well as the alleged conformism of the practice.

Peer Review as Organized Skepticism

'Organized skepticism' was coined by Robert K. Merton, America's pioneering sociologist of science, in 1942. It is the shared intellectual attitude among professional scientists that ensures detached scrutiny of beliefs and claims in terms of objective criteria. Although Merton's account arose out of an idealized view of the social relations characterizing the scientific enterprise, rather than of empirical and historical analysis of scientists' actual practices, it provides a viewpoint from which to look at the institution of peer review. Indeed, even in criticizing and expanding Merton's account of scientific norms, practicing scientist John Ziman (2000: 246) reinforces the importance of the norm of organized skepticism: "The active, systematic exercise of this norm by individual researchers is what, above all, makes science a communal enterprise. 'Peer review' is the key institution of the scientific culture." To put the point slightly differently, peer review is not only the institutional expression of the scientific norm of organized skepticism, but also a defining characteristic of what makes something 'really' scientific.

Peer review is cast in two crucial and related roles: it is assumed to guarantee good science while preserving the social contract between science and society. These roles were also identified by Merton in his original definition of organized skepticism as "both a methodological and institutional mandate" for scientific knowledge production (Merton, 1973 [1942]: 277). Merton framed this ideal as one of the four academic norms that together constitute what he called the 'ethos of science,' i.e., the institutional logic that scientific communities use for distinguishing appropriate and inappropriate values, beliefs, attitudes, and behaviors. The other three norms include (intellectual) communism, universalism, and disinterestedness.

The methodological mandate of organized skepticism is to provide an epistemic safeguard for reliable knowledge. As an opposite of dogmatism, skepticism means that all knowledge claims must be open to critical scrutiny by means of further research. Many philosophers of science (most notably, perhaps, Karl Popper, 1959) have emphasized the vital role of criticism in the advancement of learning and knowledge acquisition. This principle might be dated back to the Socratic method of asking and answering questions to stimulate critical thinking. In most general sense, peer review may we viewed as an institutionalization of this method into the conduct of science. It protects our knowledge base from contamination by error and poor argument and affords us contributions to attaining truth (Shatz, 2004).

The institutional mandate of organized skepticism is to legitimate scientific knowledge in society. It is the principle

through which science regulates itself in order to construct value, and is put into practice by a series of rational judgments and decisions. For example, Kathleen Fitzpatrick (2011) argues that the primary purpose that peer review serves today is not quality control per se, but that of institutional warranting, of conveying to e.g., university administrators that the work of their employees is appropriate and well-regarded in its field. The history of peer review can be understood as scientists' various attempts to discipline themselves according to the tacit social contract between science and society. Internalized by academics across intellectual traditions, ideals of democracy and accountability may provide pragmatic rules for peer review even in the absence of shared epistemological standards (Lamont, 2009).

Peer review unites the two mandates. As an instrument of knowledge governance in the 'republic of science' (Polanyi, 1962), peer review is claimed to be analogous to deliberative democracy. Many journal editors, for example, trying to justify the complex system, regularly make this analogy (Rennie, 2003). But it also underlies sociological and philosophical ideals of organized skepticism. If Popper's philosophy of science is read alongside his political philosophy, it is easy to see that openness to criticism is essential to democratic politics (Fuller, 2003). Similarly, Merton's ethos of science can be portrayed as an antidote to the political and ideological tutelage prevailing in the East (Elzinga, 2012).

Institutionalization of Peer Review

The Role of Royal Academies

The origin of peer review is traced to the royal academies in London and Paris in the seventeenth century. Members of the academies circulated letters among themselves or read papers in society meetings, reporting the results of their investigations with the explicit intention of eliciting response. It would be difficult to draw the line between authoring and reviewing in the context of early practices of the academies. Peer review thus emerged as a distinctive procedure only with the introduction of individual authorship, and its first instantiation was book review.

According to Mario Biagioli (2002), peer review of books developed as the result of royal privileges attributed to the very few academics to become part and parcel of the book licensing and censorship systems in the eighteenth century. It seems that the first purpose of review was to filter out books whose topic fell outside of the licensing jurisdiction of the royal academies – one that was limited to 'natural philosophy.' Skepticism was thus targeted to demarcate between what was found to be 'suitable' and what was not; this practice had little to do with quality in an epistemological or methodological sense. Biagioli's analysis shows that early peer review was anything but 'blind,' and it was precisely by being tied to specific authoritative institutions and their memberships that peer review could emerge to begin with.

Beginning in the seventeenth century, books began to be systematically reviewed also after their publication. Book reviews were published in classic 'republic of letters' periodicals like the *Journal de Savants* (established in 1665) with a view to providing the audience information about their contents and quality. These reviews had similarities to the royal 'imprimaturs' included in licensed books – they were often written by people who also worked as the royal censors – but they had clearly different status. While both kinds of reviews commented on the style, relative novelty, relevance, and other substantive qualities of the book (Biagioli, 2002), only book reviews in periodicals served organized skepticism in the sense of constructive criticism, not censorship.

The transition of peer review from an in-house disciplinary technique for specific academies to the evaluation of the work of nonmembers was connected to the development of academic journals, which brought about important changes in the role of peer review and the very meaning of 'peer.' The publishing protocols of the eighteenth century republic of letters were the first step toward redefining 'peer' in nonlocal terms, as well as toward establishing a broad scientific publication system hinged on review by academic peers. However, the republic of letters was still far from being an open system; rather, it was understood as a community having a more or less circumscribed membership (Biagioli, 2002; Broman, 2000).

The Rise of Academic Publishing

The first academic journal, *Philosophical Transactions* (established by the Royal Society of London in 1665), did not use what today would be considered proper review practices for the first 100 years. Only from 1752 were materials sent for publication subjected to inspection to a select group of members who were knowledgeable in such matters. The *Royal Society of Edinburg* seemed to have a formalized, anonymous peer review system in its *Medical Essays and Observations* starting from 1731 (Kronick, 1990). Editorial peer reviewing, however, did not evolve as a discernible movement, but as individual editors' attempts to adapt to changes in their professional environments. Historical accounts of medical publishing indicate that early peer review was meant to augment editorial expertise rather than to exercise more conventionally understood modes of quality control (Burnham, 1990). For a long time, the urgent need to fill journal pages discouraged editors from adopting any rigorous process of weeding out poor material (Abbott, 1999; Rennie, 2003; Spier, 2002).

At first, the system of refereeing presupposed a network of personal connections. The key to this system was the editor's trust in the referees, since judgments were accepted with minimal evidence (Abbott, 1999). However, it was appreciated from the start that the peer review process could not authenticate knowledge because the reviewers were not in a position to verify the claims of authors (Rennie, 2003). For authors, the newly instituted journal provided an opportunity of having competent appraisals of their work by other authoritative scientists. According to Harriet Zuckerman and Robert Merton (1971; see also Whitley, 1984), this concern of scientists with having recognition of their work by peers is central to the workings of science as a social institution. Although it no longer licenses texts, peer review has maintained the aura of the imprimatur, though one that is now about technical accuracy, not legal approbation (Biagioli, 2002).

The necessity for rigorous review has become greater as journals have had to compete on the apparent quality of their content. High rejection rate has become an indicator of

journal's quality, and journals with highest rejection rates are those that set the standards (Rennie, 2003). Even in humanities, 90% of journal editors used peer review in 1966 (Lavelle, 1966). During the latter half of twentieth century when peer review became more sophisticated and systematic, the process itself began to be investigated (Weller, 2001). While the majority of peer review processes since 1750s have been anonymous or 'single-blind' (Spier, 2002) – authors do not know who the reviewers are – the practice of blinding reviewers to the authors' identity stems from more recent concerns about bias and fairness of peer review. In sociology, for instance, the *American Sociological Review* initiated 'double-blind' reviewing in 1956, shortly after the editor had conducted a test of the affiliations and backgrounds of authors in the major sociology journals and found that "some of the reviewing was of persons rather than of submissions" (Abbott, 1999: 145). Double-blind reviewing has become standard practice across many disciplines, but the depersonalization and decontextualization of knowledge inherent in the ethic of anonymous reading remain controversial questions.

As with journals, the editorial policies of book publishing in early university presses relied on largely passive methods of manuscript selection. As a result of university presses' gradual movement from serving the university community toward a business-oriented model, review policies became more strict and substantive. The early relationship with a particular university's mission has been replaced by the goal to promote 'excellence' for the service of an international community on a field-by-field basis. Under the current system, researchers tend to seek to publish their books with the most prestigious press in the field, regardless of affiliation. The importance of unbiased, organized skepticism is visible in many academics' preference to publish at presses other than their 'own,' as institutional distance avoids suspicion of favoritism and provides 'external validation' (Fitzpatrick, 2011).

Ex ante Modes of Peer Review

As research funds became available in the nineteenth century, a new mode of peer review emerged: the process of awarding research grants on a competitive basis on the recommendation of regular or ad hoc committees of scientists, who could be considered peers of the grant competitor. Beginning in 1831, the *British Association for the Advancement of Science* developed a system of expert sectional committees to recommend expenditure of funds for specific research projects. In the United States, the *Carnegie Institution of Washington* set a similar system in 1902, followed by other granting agencies (Burnham et al., 1987). As noted by John Burnham (1990), grant peer reviewing developed independently of editorial peer reviewing, and in contrast to the latter, it seemed to spread by diffusion through personal contact and example within the scientific community.

In the post-World War II period, when a scaled-up scientific enterprise came to depend on the state for funding, the peer review of grants became firmly established. The implicit social contract underwriting public support for science was most famously institutionalized by Vannevar Bush's report for the US president in 1945. As national research funding throughout the Western world reached a steady-state dynamic in the 1970s, competition on resources intensified, and peer review procedures to select projects for funding became more strongly formalized (Elzinga, 2012; Ziman, 1994). However, the process still takes a variety of forms, and is shaped by considerations of public policy, national prosperity, and industrial needs along with scientific quality control.

Peer review has traditionally worked best *ex post* – that is, in making judgments about past performance, typically about completed work that one wishes to publish. Specific issues arise when peer reviewers are asked to assess research *ex ante* – before the research actually takes place. According to Steve Fuller (2002), special measures are needed to ensure that judgments that are fundamentally about the future – such as the direction of the research agenda and its larger public import – are not held entirely captive to the past. Indeed, the tendency for decisions to hold on peer consensus, or what psychologists call 'interrater reliability,' brings about a conservative bias of peer review, as controversial and truly novel ideas may become filtered out. Peer review may also be inherently conservative due to its reliance on existing knowledge and its gatekeepers (e.g., Horrobin, 1990). This applies to both *ex ante* and *ex post* reviewing.

As the assessment of performance has become more extensive in higher education and research policy making, peer review is being used more widely. It is increasingly employed to conduct both retrospective and forward looking evaluations of people, practices, and organizations. It is used, for example, in considerations of tenure and academic posts, to assess the performance of university departments or research programs, or to rank the relative merits of individual scholars. Because these reviews typically involve assessors examining in a summary way publications and grant-aided research activities that have already been peer-reviewed, they are sometimes referred as second-order or secondary peer review (British Academy, 2007). Whether these procedures still carry the meaning of organized skepticism can be doubted; instead of scrutinizing knowledge in a critical manner, they seem to have turned academic excellence into an ideology in itself (Readings, 1996).

Changing Contexts of Peer Review

The dominant status of peer review in modern science has resulted from the rise of academic disciplines. Between 1850 and 1900, Western science was transformed from a loose collection of local societies, research institutes and academic programs into a series of densely professionalized disciplines (Burke, 2012: 258). Following this transformation, academic disciplines have defined peers (Holbrook, 2010). During the recent decades, however, the proliferation of inter- and transdisciplinary research programs, institutes and other movements of resistance to increasing specialization have posed problems for peer review as the legitimator of knowledge. In this context, a fundamental question arises: who should count as a peer? The most obvious answer to this question thus has an obvious flaw: Disciplinary experts are often asked to serve as peer reviewers of research that may extend beyond the bounds of their expertise.

The definition of peer on disciplinary basis is insufficient also in its assumption of the universality of knowledge. After the age of positivism in social sciences, it is increasingly

recognized that domains of knowledge are not uniform across the world, nor are the means of scholarly communication. In social and behavioral sciences, in particular, cultural specificities play an important role, and contextual knowledge may be necessary for one to act as a competent peer reviewer. Moreover, despite the rise of English as the lingua franca of academic world, increasingly employed in journals, language boundaries limit the actual scope of peers.

The decline of discipline as the sole basis of defining peers is accompanied by another trend, that of democratizing expertise. It favors the extension of peer review from narrow academic elites to the full range of higher education institutions, contract researchers, as well as nonacademic members of society (e.g., Funtowicz, 2001; Fuller, 2002). This trend has questioned the democratic ideals associated with the 'ethos of science,' because it may obscure how some parts of the scientific community tend toward collusion with power elites in the political and state bureaucratic spheres.

Not only the scope of peers, but also the organizational forms of peer review are in upheaval. Open peer review, in which the reviewer and the author are known to each other, has emerged as a response to criticism of the incumbent anonymous process. Its major advantage is that it renders reviewers more accountable for their judgments. Moreover, open review through the internet provides space for new forms of community inspection. Through direct 'peer-to-peer review' practices, online communities not only bring in more voices, but make the review an open conversation. A key activity of such a system is the review of reviewers, which takes the idea of organized skepticism to a step further. However, online open review has not gained much popularity yet. An experiment undertaken by *Nature* in 2006, for example, failed: Few authors agreed to have their papers opened to public comment, and the comments that the articles received were not thorough enough to elicit editorial decisions (Fitzpatrick, 2011).

As the social system of science has become increasingly complicated, unregulated, and dispersed, peer review has been elevated to a unifying principle for a remarkably fragmented field (Biagioli, 2002). Rather than being an unambiguous medium of organized skepticism, peer review is increasingly used to serve corporate, governmental, or other objectives defined outside the autonomous sphere of science. Research is scrutinized not only for its academic quality, but also for its strategic importance and socioeconomic impacts. At the same time, measures adopted from the economic realm, like cost-benefit ratios, performance indicators, rankings, and benchmarks are used to evaluate scientific activities. Peer review is but one means among many of judging quality; rather than holding a central place in the process, peers are often asked to assist in applying evaluative indicators and interpreting their meanings in specific scholarly contexts. The meritocratic reward system of science has turned into a mixed economy of worth, in which attractiveness to external capital is valued along with the intellectual authority granted by peer review.

Conclusion

The need of critical judgment on scholarly work remains the *raison d'être* of peer review, but the purpose and beneficiaries of this practice are more ambiguous than ever before. As historians have shown, the original interests protected by peer review were primarily those of the state and its academies, not those of the broader scholarly community. Peer review underwent a slow transformation from state disciplinary techniques into academic ones, and became a symbol of the relationship between science and liberal societies (Biagioli, 2002). In the latter half of twentieth century, the expansion, dispersal, specialization, and fragmentation of scholarly knowledge have deeply changed the definition and role of peer review again, narrowing its meaning to a mode of 'gate keeping' that is not simply about quality but about policing the limits of a discursive field. Current push for inter- and transdisciplinarity, greater accountability, and profitable knowledge have left the status of peer review contentious.

An optimal peer review procedure can hardly be put on place without some trade-offs between the various values the system is asked to serve (Hackett and Chubin, 2003). From the perspective of organized skepticism, not every critical voice is constructive to the knowledge enterprise. What exactly makes intellectual critique relevant enough to require further inspection? And under what conditions does reviewing improve the outcome, and when does it do more harm than good? On the other hand, it is claimed that peer review is already overused, as scholars spend more and more time in reviewing others instead of conducting research. Questions of this kind have begun to challenge the previously unquestioned status of peer review and raised serious discussions of its future.

Perhaps the most important conceptual and practical problem of peer review is the degree to which it exhibits a conservative bias toward what is already known, and if so, should that bias be celebrated or overcome? There is a necessary creative tension between innovation and quality control, and peer review can be placed at the center of this tension (Horrobin, 1990). Ziman (1994) suggests that organized skepticism is meant as a governor on knowledge. The idea is that organized skepticism serves to slow us down so that we do not make outrageous leaps that cannot be supported. Ziman's conception of peer review might be characterized as a sort of precautionary principle for epistemology. There are, however, also 'proactionaries' (e.g., Fuller, 2002; Holbrook and Briggle, 2014), who emphasize the accountability of knowledge producers for achieving real world outcomes rather than accountability to one's disciplinary peers. It can be claimed that future wisdom relies not on certified knowledge, but on our ability to act in the face of uncertainty, ambiguity, and the unknown.

There may, in fact, be a historical shift to the contract between science and society, which undermines the original mandate of organized skepticism. The ethos of organized skepticism arose against the unquestioned 'truths' of political and religious authorities. In today's world of multiple values, beliefs – and truths – it is increasingly claimed that a new contract must ensure that scientific knowledge is not just reliable, but 'socially robust,' and that its production is seen by society to be both transparent and inclusive (e.g., Gibbons, 1999). In this context, peer review is not enough to legitimate academic work outside of the academy.

Pension Policy

Karen M Anderson, Radboud University Nijmegen, Nijmegen, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article examines why and how the first pension policies were adopted in North America, Europe, and the antipodes; identifies what the most salient dimensions of pension policy are; and discusses national policy responses to the challenges of aging, changing employment patterns, and fiscal austerity. The article also analyzes the most important explanations for cross-national differences in pension policy. The discussion centers on the affluent democracies, with references to developing countries where relevant.

Introduction

Pension policy refers to the mix of public and private programs that provide income to an individual or his/her survivors during retirement or incapacity. Pensions take myriad forms: they may be flat-rate, earnings related, lump sum, or annuities. In most affluent democracies, state provision dominates pension policy, usually supplemented by private pensions that are part of employment contracts or individual private pension products. This mix of public and private provision is central to understanding the historical development of pension policy and national responses to the current dilemmas presented by aging and fiscal austerity.

Today, pension spending is the largest item in government budgets in most Organisation for Economic Co-operation and Development (OECD) countries. In 2010, the 28 richest OECD countries spent an average of 9.3% of gross domestic product (GDP) on public pensions, with Italy topping the spending at 15.3% of GDP and Iceland spending the least at 4% of GDP. Expenditure on private pensions is also substantial, accounting for 40–50% of total pension spending in Denmark, Switzerland, and the Netherlands (figures for 2006; OECD, 2008: 42), and the proportion is rising in the OECD countries dominated by public provision. Affluent democracies thus spend considerable resources on pension policy, and the amount will continue to grow as populations age. Developing countries also devote considerable resources to pension policy, but given these countries' lower level of affluence, pensions are usually insufficient to finance complete exit from the labor force. This article examines why and how the first pension policies were adopted in North America, Europe, and the antipodes; identifies what the most salient dimensions of pension policy are; and discusses national responses to the challenges of aging, changing employment patterns, and fiscal austerity. The discussion centers on the affluent democracies with references to developing countries where relevant.

Origins and Development

Pensions have a long history. For more than a 1000 years, rulers, church officials, and governments have provided pensions to favored advisers, high-ranking officials, and military officers to reward them for loyalty and to ease them out of active service. *Pension policy*, in contrast, is a quite different thing, because it entails purposive state policies that shape the mix between public, private, and informal forms of support during old age or disability. It is only since the late 1800s and the early 1900s that a conscious pension policy in Europe, North America, and the Antipodes began, and it is only since the postwar period that pension policy emerged as a central component of state policy in the OECD countries and the developing world. Indeed, full exit from the labor force – retirement – was scarcely attainable for most groups until after the Second World War.

Until well into the twentieth century, old age and disability usually meant poverty for most people. Privileged groups, in contrast, have had access to different forms of support in old age since the Middle Ages, and the less fortunate had to make do with informal forms of support when they could no longer work. In the early industrial craft economy, older workers could move to less-demanding tasks, they could work at home, or they would simply be supported by family members. Industrialization changed all of that because it forced most workers into the wage economy, and few workers could save enough to support themselves in old age. The result was a surge in old-age poverty.

Some groups of workers did have access to pension provision, albeit usually at low levels. In North America, railroad companies were among the first to set up pension plans for their employees. In Germany, miners and railroad workers were the first to receive pension coverage, in the early- to mid-1800s. The introduction of pensions encouraged efficient retirement and promoted labor peace. Employers later used pensions for recruitment, retention, and workforce management, and occupational pension coverage spread to public servants like teachers and public utilities employees. Banking and insurance companies in the United States introduced occupational pensions in the 1920s, and the practice spread to industries like textiles, steel, paper, and printing firms.

Innovation in public pensions had to wait until the last decades of the nineteenth century when Germany introduced contributory pensions for private sector employees in 1898. Other countries were also quick to introduce public pensions, opting for poverty-preventing, flat-rate pensions: Denmark introduced means-tested pensions in 1891, New Zealand in 1898, the United Kingdom in 1908, and Sweden in 1913. Italy followed with contributory pensions for industrial workers in

1919 and France in 1932. The United States introduced contributory, earnings-related pensions for all workers in 1936.

The postwar period saw the rapid expansion of public pension schemes; benefits were upgraded and extended to more categories of workers, and several Beveridgean pioneers (New Zealand, Sweden, the United Kingdom) added earnings-related schemes to their existing flat-rate pensions. Other countries, such as the Netherlands, Denmark, and Switzerland, added or expanded mandatory or quasi-mandatory private occupational pensions. By the 1960s, most workers in the affluent democracies had access to a retirement pension that paid at least 40–60% of average wages after 40 years of service.

Analyzing Pension Policy: The Nuts and Bolts of Pensions

Pensions are complex, and understanding the interplay of different forms of public and private provisions requires some discussion of the mechanics of pension arrangements. The point of departure for most analyses of pension policy is to distinguish between state provision (the first pillar); private, employment-based pensions (the second pillar); and voluntary, private provision (the third pillar). The three pillar classification scheme was popularized by the World Bank's 1994 publication, *Averting the Old Age Crisis*. For the World Bank, the three pillars were not merely a classification scheme, but a model to be emulated (more on this below). The OECD and other international organizations have adopted the three pillar classification system, and the World Bank recently amended it to include means-tested social pensions (the 'zero pillar') and informal forms of support (the fourth pillar; Holzmann et al., 2008). The discussion here is based on the three pillar model.

Political and economic actors have been fighting over the minutiae of pension plans and the division of labor between public and private schemes since the first public and private schemes were introduced. These details of policy structure are important because they generate resources like market access for private providers, organizational resources for unions and employers charged with pension plan administration, and above all, a social right to retirement income for large groups of citizens. Moreover, the details of policy design determine the extent to which pensions, especially public ones, are redistributive or actuarially neutral.

There are four crucial aspects of pension design in all three pillars: *coverage*, *benefits*, *financing*, and *administration*. That is, pension programs (both public and private) differ concerning the groups that they provide benefits to, the generosity and type of benefit that is offered, the way in which these benefits are financed, and how they are administered. The most important dimension of variation concerning the *coverage* of public pension schemes concerns the degree of universalism. Are pensions universal in the sense that they constitute a right associated with citizenship or residence? Or are pensions selectively organized in that they are awarded on the basis of occupational status? If the example of basic pension schemes offering flat-rate benefits (for example, the state pensions in the Netherlands or Denmark) is taken, universalism means that all citizens or residents receive the same package of benefits, regardless of employment history. If public, earnings-related schemes like Sweden's are taken as examples, universalism means that all occupational groups participate in the same system – there are no special schemes for civil servants or the self-employed as there are in occupationally fragmented systems like Germany's. This means that an occupationally fragmented system like the German one provides near-universal coverage to the working population, but it does so within the confines of a system with different schemes for dependent employees, civil servants, miners, and the liberal professions.

The *coverage* of second pillar schemes depends critically on whether national regulations require or encourage employers to offer occupational pensions and employees to participate in them. In terms of compulsion, governments have three options: require employers to provide occupational pension coverage, delegate this issue to collective bargaining, or rely on voluntary provision. Switzerland is an example of the first strategy, Denmark and the Netherlands of the second, and the United Kingdom of the third.

The structure of *financing* refers to the choice between the use of taxes or contributions to fund pensions and the extent of prefunding. In a pure pay-as-you-go (PAYGO) system, the working-age population pays taxes or pension contributions that finance current pension payments. Several variations of this model are possible. For example, PAYGO schemes may include 'buffer funds' to cover fluctuations in costs caused by varying numbers of beneficiaries, contributions, and changes in benefits. The design of buffer funds differs across systems, but the basic idea is to have a financial reserve for meeting a portion of current or future pension payments. Few contributory public pension schemes are fully contribution financed. Governments often provide a subsidy financed from general revenues to the public pension scheme to cover deficits, lower contribution rates, or pay for the contributions of those who are unemployed, sick, or caring for children. Tax incentives are an important driver of second and third pillar provision. Employers can typically deduct the cost of occupational pension contributions from their taxable income, and similar provisions typically exist for individual contributions to second pillar and often, third pillar schemes.

Second pillar schemes are often fully funded in the sense that financial assets are held in trust to cover pension liabilities. The term 'full funding' is deceptive, however, because its meaning varies enormously across countries. The first key parameter that determines the definition of full funding is the distinction between group life insurance contracts and pension funds. Simplifying greatly, capital requirements are higher for insurers than for pension funds. A second key parameter is the specific nature of funding requirements: the required level of funding (as percent of liabilities), the method for calculating the value of future liabilities, and the rules governing over- and underfunding, including the ownership of surpluses and liability for deficits. Given that life insurance is regulated by European Union (EU) legislation and pension funds less so, national authorities have much leeway in tailoring pension fund legislation to national needs than they do for insurance-based occupational pension schemes.

In general, there are two methods for designing pension *benefits* in the first and second pillar. In a *defined benefit* (DB) scheme, the pension plan sponsor (the government, an

employer, or a pension fund) promises to pay an employee a specific benefit at retirement. These schemes may be prefunded or paid out of current payroll costs, but the size of the pension benefit is fixed in advance, and contribution levels are adjusted as necessary to finance pension benefits. Typical DB occupational schemes pay some percentage (often 60%) of average earnings or the final salary after 40 years of employment. Obviously, the number of years required for a full pension, the annual rate of pension accumulation, and the reference salary (final salary, average salary) used to calculate the pension level vary greatly across schemes.

In its purest form, a *defined contribution* (DC) scheme involves an individual account in which participants save for retirement. The contributions are often cofinanced or fully financed by employers. The principal and income earned by the investments in the account are then converted to an annuity at retirement or simply withdrawn at regular intervals after retirement. There is no insurance or compensation for bad financial decisions or market turmoil; returns completely depend on the level of contributions and investment performance.

These two 'pure' types obscure the ways in which the DB–DC distinction is really a continuum rather than two mutually exclusive categories. DC schemes may include elements associated with DB schemes, such as guaranteed rates of return and collective, rather than individual, membership. When these parameters apply to DC schemes, the individual bears much less risk than in a pure DC scheme. Similarly, DB schemes often incorporate features more commonly associated with DC schemes, such as making a portion of the pension dependent on investment returns.

The *administration* of pension schemes is also an important aspect of pension design. The state administers first pillar schemes, sometimes in cooperation with representatives of employers and unions (in France, for example). Second pillar schemes vary enormously in terms of administrative structure. Broadly speaking, occupational pensions may be organized as company schemes, sectoral (multiemployer) schemes, or professional schemes. This dimension determines the size and structure of the risk pool. The next key dimension is the composition of administrative boards: are employers solely responsible for pensions and entitled to make all relevant decisions, as in the United Kingdom? Or do corporatist boards with representatives of both unions and employers run things, as in Denmark, Switzerland, and the Netherlands? Are pensioners represented on these boards? As Myles and Pierson (2001) argue, these administrative boards are key actors in occupational pension policy because they make the key decisions about benefit formulas, contribution rates, eligibility, and investment policy.

Typologies of Pension Policy

Comparative analyses of pension policy typically use Esping-Andersen's typology of pension regimes as their point of departure. Esping-Andersen argues that there are 'worlds of welfare' among the affluent democracies, and pension policy is one of the core programs that the typology is based on. Esping-Andersen's classification is based on the division of labor between the state, market, and family in the division of welfare. For pensions, the core issues are the public–private mix and the quality of social rights. Universal, tax-financed, generous public pensions that crowd out private provision and reduce status differentials are the hallmarks of the social democratic pension regime. Occupationally fragmented, contribution-financed, status-preserving public pensions are the core of the corporatist/conservative regime. Market-based pensions combined with state pensions aimed at poverty prevention are the key elements of the liberal regime (Esping-Andersen, 1990). Several researchers argue that there is a fourth regime type, the Southern European regime, characterized by fragmented earnings-related pension provision, clientelistic pension policy, and informal forms of support in old age (Ferrera, 1996).

An alternative to Esping-Andersen's three regimes is to classify pension systems based on the distinction between Beveridge and Bismarck (Bonoli, 2000; Hinrichs, 2000; Ebbinghaus, 2011). The Bismarckian approach emphasizes first pillar, earnings-related pensions financed by earmarked contributions that are usually divided evenly between employers and employees. Germany is the prototypical case: pensions are part of the social insurance system that insures the incomes of wage earners. Benefits are based on 'equivalence' – the principle that benefits are strictly related to contributions. The state steps in to finance contributions for periods of nonemployment (education, child rearing) that earn pension entitlement. Bismarckian systems emphasize status maintenance because the income ceiling for pension entitlement is typically high (1.5 or 2 times the average wages) and dependent spouses are usually covered. Besides Germany, the classic Bismarckian countries are France, Austria, Belgium, and Italy (see Hinrichs and Lynch, 2010, for more).

The Beveridgean approach – named for William Beveridge, author of the influential 1942 report that provided the blueprint for the postwar British welfare state – emphasizes universal, tax-financed, flat-rate provision aimed at poverty alleviation. The English-speaking countries (except for the United States) and the Nordic countries exemplify Beveridgean principles because the state pension, either alone or in combination with means-tested supplements, is sufficient to lift the poorest pensioners out of poverty. Beveridgean countries such as the United Kingdom, Australia, Denmark, Switzerland, and the Netherlands later added extensive private occupational coverage to the basic security provided by their state pensions. According to Hinrichs (2000), Sweden, Finland, Norway, and Canada began as Beveridgean systems because they introduced basic security pensions in the first half of the twentieth century, but later added public earnings-related pensions that moved them to the Bismarckian category.

The Bismarckian–Beveridge classification system has gained ground in recent scholarship, informing several important analyses of pension policy (see for example, Bonoli, 2000; Ebbinghaus, 2011; Häusermann, 2010). The chief virtue of this approach is that it emphasizes the institutional goals of public pension institutions (basic security or status maintenance) and the political coalitions that constructed them and continue to maintain them. Esping-Andersen's threefold typology has drawn criticism for being too static and too focused on the outcomes of decommodification and social stratification, yet

the move toward the Bismarck–Beveridge dichotomy in recent research often obscures more than it illuminates. One of the strengths of Esping-Andersen's typology is that it distinguishes between conservative and social democratic goals in welfare policy. Center-right parties preferred status-maintaining social policies that also reinforced traditional family structures, so they adopted Bismarckian principles. Nordic social democrats usually wanted something else: universal social policies that would create cross-class solidarities and promote individual autonomy. These distinctions between social democratic and conservative/corporatist pension policies disappear in the Bismarck–Beveridge dichotomy.

Explaining Institutional Variation

Scholarly attempts to classify pension systems according to twofold or threefold typologies impose order on tremendous institutional diversity. The key questions animating research in pension policy concern the timing and content of early public pension programs (Beveridge vs Bismarck), the contours of the expansion and consolidation of public programs, and the nature of the public–private mix in pension policy. Since the 1990s, researchers have been preoccupied with the issue of *pension reform*, investigating the causes and consequences of rolling back or adjusting pension arrangements that have been in place for several, if not many, decades.

The Modernization Thesis

Some of the most influential early analyses of the development of pension policy attributed the development of pension policies in the developed countries to the pressures arising from industrialization and democratization (Flora and Alber, 1981). Industrialization forced laborers out of agriculture and small-scale, craft-based industries and into wage labor in large factories. With industrialization, existing informal forms of support for older workers disappeared. In the early capitalist period, older workers performed less-demanding tasks within small, family-owned enterprises, or they were supported by family members. Craftsmen also usually owned their enterprises, and this capital could be used as a source of support in old age. Employment in large-scale industries at low wages meant that few could afford to save for their old age; indeed, most people worked until they no longer could, because of disability, old age, or both. Thus industrialization created a growing class of elderly poor, and existing poor relief policies could not keep pace. The earliest public pension schemes, whether Beveridgean or Bismarckian, were created to address the problem of old-age poverty, at least in part. Bismarck's pioneering pension reform in 1889 aimed not only to reduce poverty among the aged but also to pacify the growing industrial labor force.

Other researchers working within this perspective highlight the role of economic growth and demographic change in driving the expansion of social protection after the introduction of the first programs. Economic growth generates additional resources that can be spent on social policies like pensions; a high-level of socioeconomic development is thus a prerequisite for the introduction of social insurance schemes like old-age pensions, and it is the growing wealth of the country that is one of the most important factors driving their expansion. Another variation of this perspective emphasizes demographic change, pointing to the correlation between the growing size of the elderly population in affluent democracies and spending on programs targeted at the elderly like old-age pensions. Wilensky (1975) was the first to argue that the relationship between economic developments and welfare state effort was mediated by the size of the elderly population. Recent variants of this argument include Tepe and Vanhuysse (2009).

The modernization perspective has been widely criticized for its emphasis on more or less automatic state policy responses to objective pressures (see, for example, Orloff, 1993; Lynch, 2006). Explanations of pension policy development based on modernization theory are by their very nature functionalist arguments; they emphasize the fact that nearly all affluent democracies introduced public pension schemes by the first half of the twentieth century and expanded them after the Second World War. However, the content of these policies and their effects on income inequality and social stratification are left unexamined. This means that political ideologies and distributional conflict are largely absent in this approach.

Politics Matters

There is a large and influential literature that builds on modernization theory by arguing that political processes mediate the pressures caused by industrialization. Whereas modernization theorists emphasize the similar responses of democratizing states to the social problems created by industrialization, proponents of politics-centered explanations of pension policy development highlight the crucial role played by political mobilization in shaping outcomes. Thus the extension of the suffrage in Europe, North America, and the antipodes created opportunities for the political representation of groups favoring state-led social reform. At the same time, workers and employers began to organize, building powerful organizations to represent their interests in workplace negotiations and electoral politics. Korpi (1983), for example, argues that the structures of welfare state policies, including pension policy, are the result of the 'democratic class struggle.' The working class, represented in the workplace by trade unions and in the political arena by social democratic parties, drew on its 'power resources' to press for social policy reforms in the democratic political process. Organized business is generally viewed to be hostile to such reform efforts, preferring to retain as much control as possible over working conditions (see Swenson, 2002; Mares, 2003 for arguments that challenge this view). The character of welfare state policies like pensions is thus the outcome of the balance of power between organized labor and capital. In countries where the working class was powerful, the state introduced generous public pensions that crowded out private provision. Esping-Andersen's (1990) typology of pension regimes is an influential application of power resources theory. As discussed above, it is the influence of class actors working within the democratic political system, as well as their ability to build coalitions across class lines, that

is the most important cause of variations in the structure of pension regimes.

Institutionalism

The renaissance of scholarship concerning the role of political institutions in shaping political processes and outcomes has been an important focus of recent research concerning the development of pension policy. This literature is large and varied, but contributions to it share the assumption that stable governance arrangements structure political outcomes. These governance arrangements, whether they are constitutional structures, industrial relations systems, or party systems, form the institutional context within which political actors formulate their interests and choose their political strategies. Understanding the development of pension policy thus requires investigation of the ways that institutional context shapes both the goals and strategies of advocates and opponents of pension reform.

Research concerning the role of constitutional design on welfare state outcomes has generated important insights about the constraints and opportunities presented by formal political institutions on policy making. Immergut's (1992) analysis of the role of veto points in the development of health care policy in Western Europe is the basis for a large literature that emphasizes the role of veto points in shaping the contours of pension policy (see, for example, Bonoli, 2000; Immergut et al., 2007). Veto points refer to the opportunities created by constitutional rules for reform opponents to block or weaken legislation. Federal systems like the United States, Switzerland, and Germany offer more veto opportunities than Westminster systems like the United Kingdom. The more hurdles a legislative proposal must pass through, the more difficult it is for the executive to pass a reform. Other scholars working within the institutionalist perspective stress the role of political competition in the making of pension policy (Lynch, 2006; Orloff, 1993).

A particularly influential variant of the institutionalist perspective is the policy feedback approach advanced by Pierson (1994, 2001) and others (Orloff, 1993). The central assumption of this approach is that policies have political effects and thus shape future political processes. Applied to the welfare state and pension policy, policy feedbacks include incentives for interest group activity, the emergence of strong support coalitions, coordination effects, and changing expectations about the role of government in social protection. Extensive public pensions generate their own sources of support because interest groups are created to protect the beneficiaries of these programs, individuals plan their retirement around the existence of these programs, and over time, the public accepts the role of government in old-age provision. Pensions are everyone's favorite example of path dependence, because the feedbacks that create policy stability are often very strong. Indeed, researchers point to the strong potential for 'lock-in' effects in pension policy (Myles and Pierson, 2001). Because pension policies entail long-term commitments affecting individual and family incomes, they are particularly stable and resistant to retrenchment.

Pension Policy Outside the OECD

The developing world is not immune to the challenges associated with creating pension policies that address poverty and income maintenance in old age, but the nature of these challenges is much different than in the OECD. Whereas the OECD countries must reform their mature pension systems to deal with aging and fiscal austerity, the developing countries face the challenge of expanding policies that offer incomplete and/or inadequate protection from old-age poverty. There is enormous variation in pension policy in the developing world. In general, however, they face four common challenges. First, mandatory coverage is fairly low, whether in the first or second pillar. Second, benefits are usually insufficient to permit complete exit from the labor force. Third, informal means of support in old age play an important role in ensuring the livelihood of the elderly. Finally, privatization has progressed further than in the OECD.

The former communist countries inherited pension systems that were not well suited to the market economy. The transition to a market economy undermined full employment and state-sponsored social benefits like pensions. State pensions were retained in most of the Central and East European countries, but spending exploded in the wake of high unemployment and labor shedding. Most of the transition countries privatized large portions of their retirement provision, resulting in lower benefits for future retirees and an increase in individual exposure to investment risks (see Orenstein, 2008; Müller, 2001).

The Asian/Pacific countries did not introduce pension schemes until the 1950s, and the expansion of coverage and benefit adequacy has been uneven. Public provision dominates, and benefits are generous in China, Vietnam, and Pakistan. However, coverage is low: 13% of the economically active in South Asia and 35% in East Asia. (see OECD, 2009), and many systems allow participants to withdraw savings before retirement or to receive their pension as a lump sum. Like Latin America (see below) the Asian/Pacific countries are experiencing a rapid demographic transition. As the old-age dependency ratio rises, it will be even more difficult for these incomplete pension systems to prevent poverty in old age.

The first pension schemes were introduced in Latin America in the 1920s (Chile and Ecuador), and the rest of the region followed between 1930 and the 1950s. Since the 1980s, the region has been known for far-reaching privatization. Chile transformed its public, PAYGO scheme into a system of private, individual accounts in 1982. Nine other countries have implemented some form of privatization, including Mexico, Bolivia, El Salvador, and Peru. Despite these reforms, coverage is patchy, and benefits will be inadequate for large groups of pensioners. Indeed, Latin America faces its own set of challenges caused by aging: falling birth rates and rising longevity mean an increasing old-age dependency ratio. In one generation, Latin America will face demographic constraints similar to those currently experienced in Europe (Jackson et al., 2009).

The Future of Pension Policy

Two challenges dominate debates about the future direction of pension policy. First, the dramatic aging of populations creates

unprecedented pressure on social protection institutions that were designed for a high-fertility, high-employment, high-growth socioeconomic context. According to the most recent projections of the European Union, the proportion of people aged 65 years and older in the EU-27 will increase from 17% in 2007 to 30% in 2060. Moreover, the ratio of elderly persons to working-age persons (age 15–64 years) will increase from 1:4 today to 1:2 in 2060. Population aging coincides with a second challenge: rapidly changing labor markets and employment patterns. Full employment for standard, full-time workers seems to be a thing of the past. Instead, 'dual' or 'segmented' labor markets have emerged in many European economies (see, for example, Palier and Thelen, 2010), characterized by high levels of youth unemployment, the expansion of part-time and atypical work, and persistent long-term unemployment.

The heart of the 'pension problem' lies in the fact that fewer and fewer workers will be financing more and more pensioners. The more that pensioners believe their pension rights to be earned (on the basis of contributions on earnings) and therefore to have the status of rights, the less likely they will be to support pension reductions. This dependency of older generations on younger ones often generates severe distributional conflict when revenues are not sufficient to cover pension costs, because neither pensioners nor workers are likely to want to cover the funding shortfall. Thus the 'contract between the generations' is just as likely to unleash intergenerational conflict as it is to foster intergenerational solidarity.

A second challenge related to pension reform concerns growing income inequality among pensioners and between pensioners and the working population (obviously these two trends take different forms in different countries). The OECD reports that in the mid-2000s, people aged 65 years and older had an average income that was 82.4% of average population income. Those aged 66–75 years had higher average incomes than those aged 76 years and older. Women are more likely to be represented in the over 75 group because of their higher life expectancy, and their nonstandard earnings biographies (part-time, career breaks, etc.) result in lower earnings and therefore lower pensions. The OECD also reports that in 13 of the 25 OECD countries studied, the incomes of the elderly grew more quickly than that of the working population between the mid-1980s and the mid-2000s (OECD, 2011: 146).

These statistics point to growing pensioner affluence, even if average pensioner incomes remain below the average income for the entire population. In other words, pensioners have an increased capacity to maintain an autonomous household and to enjoy security in terms of health care and housing. At the same time, however, the numbers of frail elderly are growing, as are the numbers of females older than 75 years with low incomes. In order to avoid either cutting benefit levels significantly or substantially increasing contributions, many policy makers look to some form of funding as a way to make future pension payments more affordable. However, the shift from a PAYGO to a fully or partially funded system is difficult, because current contributors in a PAYGO system are already paying for the pensions of current retirees. Thus, in order to introduce funding, current workers would have to pay higher contributions in order to fund both current PAYGO pensions and their own future funded pensions. This double burden of the transition cohort of pensioners is known as the 'double payment problem' (see Pierson, 1994) and it is one of the primary mechanisms that 'locks' policy makers into maintaining PAYGO financing.

Policy makers in the OECD have responded to reform pressures by adopting parametric reforms that modestly reduce benefits and are sometimes accompanied by the introduction of funded private provision. One important policy measure has been to try to tighten the link between benefits and contributions by changing benefit formulas so that benefits depend more directly on contributions. Examples include increasing the reference period for the calculation of benefits and requiring longer qualifying periods. Other ways to reduce pension costs include changing the basis for the benefit calculation from gross to net wages, lowering the replacement rate, changing the formulas for benefit indexation or the tax status of benefits, or even simply skipping or delaying benefit indexation.

A different approach to addressing the financial sustainability of public pension systems has been to increase the revenues of pension systems, for example, by increasing the contribution made by general tax revenues or special taxes (value-added tax or energy taxes, for example) to pension systems – although these approaches, obviously, increase the general tax burden. Governments have also proposed fusing separate special pension schemes in order to eliminate inequities, reduce administrative costs, and increase the coverage of the system to include greater proportions of higher income persons, such as by rolling civil servants into the general pension schemes or eliminating special privileges for public sector workers.

In the multipillar systems of the United Kingdom, the Netherlands, and Switzerland, the financial crises of the 2000s and 2010s have prompted reductions in private occupational pensions. In the United States and United Kingdom, there has been a rapid movement from DB to DC plans over the past decades (Bridgen and Meyer, 2005). In the public sector, however, efforts to change the rules of the game for pension benefits are more explicitly political and tend to involve more overt political conflict. Regardless of whether the decision to convert a benefit scheme from DB to DC is made by governmental authorities is an outcome of collective bargaining, or is the result of what the private market is willing to offer in terms of individual pension policies, the shift from DB to DC exposes individuals to more market risk. If returns to investments are high, such a risk may prove beneficial; if not, pensioners will experience lower retirement income (see also Anderson, 2011).

Abstract

This article offers a critical review of research in organizational behavior from an interactionist perspective: we consider the reciprocal influence between personal characteristics and the organizational context. Specifically, some situations are stronger than others, some people's behavior is more consistent across situations, some people can influence situations more than others, and people select themselves into situations that suit their preferences. We illustrate the value of this perspective by identifying person–situation interactions that are relevant to a set of currently vibrant theories: organizational culture, demography, leadership, and creativity. Emerging from this review is a greater appreciation for the richness of behavior in organizations and the challenge of understanding and managing its complexities.

This article offers a critical review of research in organizational behavior from an interactionist perspective: we consider the reciprocal influence between personal characteristics and the organizational context. Specifically, some situations are stronger than others, some people's behavior is more consistent across situations, some people can influence situations more than others, and people select themselves into situations that suit their preferences. We illustrate the value of this perspective by identifying person–situation interactions that are relevant to a set of currently vibrant theories: organizational culture, demography, leadership, and creativity. Emerging from this review is a greater appreciation for the richness of behavior in organizations and the challenge of understanding and managing its complexities.

Organizational researchers study how individuals and organizations interact with their environment to accomplish both individual and collective goals. People are able to accomplish goals in organizations that they would be unable to accomplish alone, and they spend large portions of their lives interacting in organizational contexts. The complexities that emerge from bringing people together in organizational settings, therefore, provide a fascinating lens into the human experience. Organizational research brings together psychology, sociology, economics, and anthropology to examine both individual-level processes at work, as well as the organizational-level processes that dictate how firms relate to each other and their environment.

Reflecting this focus on both individuals and organizations, the field is split between 'macro' organizational behavior, drawing upon organizational sociology, and 'micro' organizational behavior, drawing upon social, personality, and industrial-organizational psychology. Macro-organizational behavior is concerned with the various strategies organizations use to adjust to their environment, such as the development of networks between firms. In contrast, micro-organizational behavior is concerned with the way personal characteristics combine with contextual features such as task, group, and organizational characteristics to predict work outcomes. Though the strength and uniqueness of organizational behavior rests on the equal emphasis of both individual and organizational processes and the utilization of a variety of research methods that cross disparate levels of analysis, our focus in this article is on micro-theory and research. Excellent reviews of macro-organizational theory can be found elsewhere in this collection (*see* Organization: Overview; Administration in Organizations; Organizational Control; Organizations and Culture; Organizations: Authority and Power) and in Carroll and Hannan (2000) and Scott (1998).

Micro-theory: Person–Situation Interactions

Micro-organizational behavior examines both personal and situational characteristics and, as in the field of psychology, researchers debate the relative utility of each in explaining behavior. Some have emphasized the stability of attitudes and behaviors over time. For example, a person's satisfaction with his or her job remains relatively stable over years and even decades (Staw and Ross, 1985). From this perspective, individual characteristics are the best predictors of behavior since they derive from personal dispositions that remain stable over time and across situations. Others have criticized this view and posited that organizations should be conceptualized as 'strong' situations that are powerful enough to shape individual behavior (e.g., Davis-Blake and Pfeffer, 1989). In strong situations individual differences are unlikely to be expressed. Instead, people learn appropriate attitudes and behaviors from their co-workers, established norms, and organizational practices and procedures; these social influence processes are presumed to predict individual behavior better than are personal characteristics.

Researchers have typically considered personal and situational factors in isolation from one another, but a complete understanding of organizational behavior requires their simultaneous consideration. An interactional approach is more complex than a mere additive melding of personal and situational characteristics because it attempts to represent both personal and situational factors and their reciprocal influence.

Interactions between personal and situational characteristics may take at least four forms. First, as specified above, some situations are stronger than others, leading to different levels of behavioral uniformity. Second, work situations do not affect everyone in the same way; some people's behavior is more consistent across varying situations. Third, certain people,

such as those exhibiting 'charismatic' leadership, can influence situations more than others. Finally, people do not select into situations randomly, but rather, into situations in which they think their attitudes and behaviors will be appreciated. Developing a complete theory of behavior in organizations, then, requires moving from considering personal and situational factors in isolation to considering the complexity and diversity of possible person–situation interactions and their effects on work outcomes. We illustrate this by identifying the types of person–situation interactions that are relevant to a set of vibrant research domains within organizational behavior: organizational culture, demography, leadership, and creativity.

Organizational Culture: Selection, Socialization, and Person–Culture Fit

Research on organizational culture has demonstrated that norms and values can shape individual behavior. Recent research has also demonstrated that behavior can be predicted by understanding how personal characteristics interact with cultural context. Below we discuss the four types of person–situation interactions as they relate to organizational culture.

Organizational Culture as Strong Situation

Though researchers agree that organizational culture is meaningful and important, they do not agree about how to define and measure it. Organizational culture research typically draws upon theories in anthropology or cross-cultural psychology and uses ethnographic or quantitative methodologies. Some researchers have emphasized shared values and meaning (O'Reilly et al., 1991) while others have emphasized the ambiguity of cultural values and the existence of subcultures (Martin, 1992). Most agree that the existence of different perceptions among members does not preclude the existence of shared assumptions. Organizational culture can be understood as a system of shared values and norms that define what is important and how organizational members ought to feel and behave. Through members' clarity about organizational objectives and their willingness to work toward these objectives, culture influences the attainment of valued organizational goals by enhancing an organization's ability to execute its strategy. This conceptualization focuses on two primary aspects of culture: first, the extent to which agreement and intensity exist about values and norms (culture strength), and, second, the extent to which these norms and values differ across settings in important ways (culture content).

Culture content refers to shared values and norms that define desirable behavior in the organization. For example, some cultures may stress the value of being a 'team player' while others may emphasize independence. For a culture to be strong, members must agree about which values are important and be willing to enforce them strenuously. Members of an organization may agree that they value, for example, being cooperative, but unless unequivocal and salient consequences result from compliance (e.g., cooperating with co-workers) and non-compliance (e.g., competing with or undercutting co-workers), the culture cannot be characterized as strong. A strong culture is characterized by social control in that members both agree about and are willing to enforce values and norms, even if such enforcement violates hierarchical lines of authority. Further, greater behavioral homogeneity among members, for better or worse, should be observed in stronger organizational cultures.

Cultural values are conveyed to members through the socialization processes that new recruits experience when they enter an organization. Though socialization often takes the form of training and contributes to increased task knowledge, information about the norms of the organization is also transmitted through training and other types of socialization (Morrison, 1993). Interestingly, such normative information appears to be transmitted very early in new recruits' membership since cultural fit changes little after members' first year (e.g., Rynes and Gerhart, 1990).

Behavioral Consistency Across Various Organizational Cultures

Although culture influences members' behavior, they are not merely passive recipients of social control. Individual characteristics may interact with the organization's culture to predict important behavioral and work outcomes. Research on person–organization fit, defined broadly as the compatibility between people and the organizations for which they work (Kristof, 1996) has focused primarily on congruence between patterns of organizational values and patterns of individual values. New employees whose values more closely match those of the organization view it as more attractive, are more likely to join when made an offer, are able to adjust to it more rapidly, perform better, are more satisfied, and remain with it longer (e.g., Chatman, 1991).

But, just as organizational cultures may differentially affect behavior, people may also differ in the extent to which their behavior is shaped by an organization's culture. For instance, compared to individualists, cooperative people were more responsive to the individualistic or collectivistic norms characterizing their organization's culture, and exhibited greater behavioral adaptation to each across the two types of organizational cultures (Chatman and Barsade, 1995). Thus, congruence models, which presume an additive equivalence of person and situation factors and assume that greater congruence is always better, cannot fully explain behavior in organizations. Instead, a focus on mismatches between person and organization characteristics that challenge people to either act in accordance with the culture and thereby contradict enduring personal tendencies, or vice versa, might generate insight into such interactions.

Future research might focus on the set of characteristics, such as cooperation, self-monitoring, and self-esteem, that contribute to people's flexibility across situations. Identifying such characteristics could improve predictions of the behavioral expression of person characteristics both across time and across situations, and in particular, the extent to which an organization's culture and processes will influence member behavior. Research might investigate other organizationally relevant matches and mismatches to understand how different situations influence person–situation interactions. For example, examining mismatches between honest people

and dishonest organizations may help to identify if and when good people 'turn bad.'

Individuals' Influence Over Organizational Culture

Founders and senior executives, who have legitimacy and authority, may be the most influential individuals in an organization. The person who creates the organization has significant impact on the strategies that the group develops to survive, and these are often preserved in the organization's values, practices, and promotion patterns well past the individuals' actual presence. Ironically, newcomers, who are at the other end of the spectrum in terms of authority and legitimacy from founders, may also exert a great deal of influence on culture. This influence may be indirect; research has shown that the process of recruiting new members, including emphasizing an organization's attractions, strengthens current members' connection to their organization (Sutton and Louis, 1987), and can exert mutual learning of the organizational culture (March, 1991). An organization's culture may also be transformed by the entrance and exit of its members. Thus, the strength of an organization's culture may depend on the individual mobility of its members. Using simulation methods, organizations' length of service distributions have been examined as indicators of the extent to which members have been socialized into the culture's norms and values. This research has shown that variations in service distributions are positively associated with heterogeneity in organizational culture due to three distinct cultural processes: socialization, group cohesiveness, and common historical experiences (Carroll and Harrison, 1998).

Situation Selection Based on Organizational Culture

Schneider (1987) developed the Attraction–Selection–Attrition (ASA) model, which posits that the key factor influencing the relationship between people and organizations is the fit between individual personality and the modal personality represented in the organization. People are differentially attracted to organizations on the basis of the anticipated fit between their own characteristics, such as personality traits, and organizational characteristics, such as culture (e.g., Cable and Judge, 1997). Job seekers take an active role in the recruitment process and are attracted to careers and organizations reflecting their personal values and interests. Further, organizations have developed formal and informal strategies to identify and select recruits who will be compatible with their goals and working environment, elements that are strongly influenced by an organization's cultural values. For instance, rather than focusing on job-related criteria, selection appears to be based on such socially based criteria as 'personal chemistry,' and fit with the organization's values.

Organizational Demography

People may differ from each other in many ways that are both observable and unobservable. Members' observable demographic characteristics constitute a context for every other individual in the organization. For instance, a lone newcomer in an organization of established members may have a very different experience than a newcomer entering an organization characterized by members with varying tenure. Given the dramatic changes in US labor force demography over the past decade, relational demography, or the distribution of demographic characteristics within organizations, has become an active area of research.

Research on organizational demography improves upon past research on employee turnover. Turnover typically indicates a discrete departure event while demography focuses on length of service and rate of departure by taking into account the distribution of people by the length of time they have spent in the organization. This distribution can be influenced by a host of factors including personnel policies, technology, and the degree of unionization in the workforce (Pfeffer, 1983). Most research on observable differences has examined the effect of demographic heterogeneity versus homogeneity on performance and has yielded mixed results (see Williams and O'Reilly, 1998 for a comprehensive review). Some studies have demonstrated the positive effects of demographic heterogeneity for increasing the number of novel perspectives that can be used to solve difficult problems, increasing an organization's network of contacts, and facilitating organizational change. However, demographic heterogeneity may also lead to communication problems, less social integration in workgroups and greater turnover (e.g., Tsui et al., 1992). Demographic distribution among members across various attributes is an important situational factor that deserves further research since it can influence behavior differently depending on an individual's own demographic profile.

Behavioral Consistency Across Demographically Heterogeneous Workgroups

Research suggests that an organization's culture may influence the relationship between demographic diversity and work outcomes. For example, the purported benefits of a demographically diverse workforce are more likely to emerge in collectivistic organizations that make organizational membership more salient than membership in a demographic category (Chatman et al., 1998). An organization's culture may dictate the extent to which members view certain demographic characteristics as valuable and others as associated with lower status within an organization's informal social system (Spataro, 2000). Furthermore, each attribute, such as tenure, race, or sex heterogeneity within a group, may differentially influence individual behavior and the combinations of various attributes can result in 'fault lines' which become stronger as more attributes align themselves in the same way (Lau and Murnighan, 1998).

One explanation for the lack of clarity about the benefits and detriments of diversity is that researchers have neglected to consider key mediating processes between demographic composition and performance. As shown in one recent study, heterogeneous groups initially created norms fostering independence rather than cooperation among members, but cooperative norms subsequently mediated the relationship

between group demographics and performance (Chatman and Flynn, 2001). Similarly, a group's level of conflict influenced the impact of demographic heterogeneity on performance (Jehn et al., 1999).

Leadership

Some Individuals Can Effect Change More Than Others

Early leadership research focused on the physiological and psychological traits thought to be associated with exceptional leaders. These 'great man' theories of leadership examined the effects of personal characteristics such as height, physical appearance, and intelligence on leaders' emergence and effectiveness. This stream of research has its counterpart in more current studies examining the effects of self-confidence, extraversion, and energy level (e.g., House, 1988). The aim of this approach has been to identify a leadership personality. However, it leaves many crucial questions unanswered, such as whether certain personal characteristics become more important than others depending on the organizational context, and why, regardless of formal authority, followers perceive some people as leaders and not others.

Contingency theories of leadership were advanced to explain how certain personal characteristics made a leader effective in certain situations (e.g., House and Baetz, 1979). For example, leaders who initiated structure raised the productivity and satisfaction of a group working on a boring or simple task but lowered the productivity and satisfaction of a group working on a complex task, while a considerate leader raised the satisfaction and productivity of a group engaged in a boring task but had little effect on a group engaged in a task they found intrinsically interesting. Additionally, research showed that allowing members to participate in decision making increased commitment but depended on the amount of trust the leader had in his or her subordinates as well as the urgency of task completion (Vroom and Jago, 1978). Thus, contingency theories of leadership were more comprehensive than trait theories; however, they still did not account for the interactive effects of leader characteristics and their situational contexts.

Recent research has focused on charismatic and transformational leadership, demonstrating that some individuals influence situations more than others. This research takes an interactional approach by conceptualizing leadership as a personal relationship between the leader and his or her followers. A leader must have certain interpersonal skills in order to inspire followers to set aside their goals and to pursue a common vision. Charismatic leaders are thought to have the ability to change their circumstances by increasing followers' motivation and commitment and, sometimes, to change the direction of the entire organization (e.g., Meindl et al., 1985). However, a leader is only charismatic if followers recognize him or her as such; followers must identify with the vision articulated by the leader. In one particularly exhaustive laboratory study of charismatic leadership (Howell and Frost, 1989), confederates were trained to display qualities of a charismatic leader, such as projecting a dominant presence, articulating a large overarching goal, and displaying extreme confidence in followers' ability to accomplish this goal. In addition, norms were created in each group for either high or low productivity. In contrast to participants working under a considerate or structuring leader, participants working under the charismatic leader displayed higher task performance regardless of the group productivity norm. This finding suggests that leaders mold their styles in response to the situation. Moreover, some leaders are capable of changing the situation itself by changing followers' perceptions and motivation.

Leadership as a Function of the Strength of the Situation

Some researchers have been skeptical of a leader's ability to change situations, and have suggested that leadership is far more situationally determined than might have been assumed. The attributional theory of leadership suggests that because people tend to associate certain behaviors with those of a leader, leadership qualities will be attributed to a person displaying these behaviors (Calder, 1977). Various biases emerge from this attribution, however. For instance, individuals tend to overestimate the amount of control a leader has over events that are, in fact, random or uncontrollable (Pfeffer, 1977). Furthermore, a leader will be given more credit when situations are unfavorable (Meindl et al., 1985). Individuals' lay conceptions of leadership can be used or misused for the purposes of organizational impression management (Ginzel et al., 1993). In sum, leadership research has focused more on contexts and followers rather than on the characteristics of a focal leader. Future research might examine whether leaders reflect the personal characteristics of their followers or complement their weaknesses, if some followers have a greater psychological need for leadership than others, and the various substitutes for leadership, or how people can be compelled to lead themselves.

Creativity and Innovation

Research on creativity, like leadership, has moved from emphasizing traits, to considering the organizational context as well as the interaction between the two. Creativity is generally viewed as distinct from innovation. Creativity occurs at the individual level, and refers to the generation of ideas that are both novel and useful. Innovation refers to the process of implementing these ideas at the organizational level.

Some People Are More Creative Across Situations Than Others

Early creativity research focused on the personality traits associated with individuals who had made creative contributions in their respective fields. People who have a wide variety of interests, are attracted to complex tasks, tolerant of ambiguity, and self-confident perform more creatively (e.g., Barron and Harrington, 1981). However, trait research ignores how organizational contexts influence people's ability to perform creatively.

Some Situations Foster More Creativity Than Others

The degree to which one's job encourages intrinsic versus extrinsic motivation affects one's creative performance. Early

studies suggested that when people worked on tasks that they found intrinsically interesting, adding an extrinsic reward lowered their interest in performing the task for its own sake (Deci, 1971). More recent studies in organizational settings showed that individuals were most creative when they were intrinsically motivated. This intrinsic interest led them to stay focused, persist longer to complete difficult tasks, to 'play' with ideas, and suggest novel solutions (Amabile, 1988). This suggests that the situational factors that are associated with decreases in intrinsic motivation, such as a controlling supervisory style, and an emphasis on external rewards, may indirectly diminish people's creative potential.

Organizational culture also influences creativity and innovation. Organizations that have mechanisms to express confidence in members, and communicate this confidence through the culture's core values, increase creativity among members (Kanter, 1988). These findings are supported by a recent ethnography of a product design firm, IDEO, which creates new products by taking technologies from one industry and applying them in other industries where these technologies are unknown (Hargadon and Sutton, 1997). At IDEO, employees are encouraged to create analogies between past technological solutions and current problems and to share them in brainstorming sessions. Further, employees are selected who have unique hobbies or skills that can be used to solve design problems.

Employees who have traits associated with creativity are more likely to thrive in organizations such as IDEO, which place an emphasis on creative performance. For example, employees produced the most creative work when they possessed the appropriate personal characteristics, were working on complex assignments, and were supervised in a supportive, noncontrolling fashion (Oldham and Cummings, 1996). While the possibility that organizations can manage creativity through the use of a strong culture appears promising (Flynn and Chatman, 2001), some worry that mechanisms of social control will stifle, not encourage creativity (Nemeth and Staw, 1989). Future researchers might examine how organizations can achieve harmony and cohesion without sacrificing the flexibility and constructive conflict necessary for creativity and innovation. Many believe that creativity and innovation are the last sustainable competitive advantages and as such these issues will continue to generate a great deal of interest.

Conclusion

As theorists endeavor to develop a complete understanding of behavior in organizations, the analysis of both personal and situational factors, as conjoined units of behavior, will become increasingly fundamental to organizational studies. Person–situation interactions are much more complex than the simple addition of personal and situational characteristics, and these interactions may take a variety of forms. Some people are more responsive to situations than others, some situations can shape behavior to a greater degree than others, and some people have the unique capability to shape situations to their advantage or that of the organization. Furthermore, group members' personal characteristics may constitute the situational context as every individual responds to the personal or demographic characteristics of every other individual in the organization (Carroll and Harrison, 1998; Tsui et al., 1992). These interactions are both complex and diverse: hence the field of organizational behavior must necessarily reflect this diversity. It will become increasingly important to observe these interactions over time. Since people and situations adjust to each other, cross-sectional research will not capture the dynamic interplay between the two. By pursuing interactional research over time, organizational behavior will increasingly evolve into a field that is as vibrant as the organizations it seeks to understand.

Perception of Action Space: Using Multiple Frames of Reference

Carl Gabbard, Texas A&M University, College Station, TX, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by C.L. Colby, volume 16, pp. 11205–11209, © 2001, Elsevier Ltd.

Abstract

Our ability to move through and act on the environment around us is driven by, seemingly effortless, yet quite complex systems. The focus of this article is on the visuospatial frames of reference that are used to plan and execute actions in peripersonal and extrapersonal space. The particular representation of space in use at any time depends on the task the individual is trying to perform. Spatial locations of objects in the surrounding environment can be perceived based on observer-centered coordinates and on object-centered coordinates known, respectively, as egocentric and allocentric frames of reference. The discussion includes basic terms and a review of selected research on neural underpinnings, and typical and atypical behaviors.

Most of us take for granted our ability to navigate through the environment and when needed or intending, to interact with objects. For example, the seemingly effortless way in which we reach for an object belies the complex computations that go into determining its location. The psychological and neural processes that underlie our visuospatial abilities have been extensively explored in humans and animals, but to this day remain somewhat of a mystery. This article describes selected psychological and neural aspects of spatial perception with particular focus on how we use visual frames of reference to guide our actions.

Basic Terms Associated with Perceiving and Understanding the Space around Us

Spatial Cognition

Underscoring the perception and action on objects in space involves a degree of *spatial cognition.* Although several definitions have been suggested, the general assumption is that it involves representing, organizing, understanding, and interacting with stimuli in the environment.

Spatial cognition involves not one but many specific abilities. Within the visual domain these include locating points in space, determining the orientation of lines and objects, assessing location in depth, appreciating geometric relations between objects, and processing motion, including motion in depth. These spatial skills can be applied to mentally representing (imagining) objects as well as acting on external stimuli (*see* Mental Imagery, Visual Cognition).

According to Burgess (2008), spatial cognition embraces an ensemble of representations supporting visuospatial perception, mental imagery, spatial memory, and navigation. *Visuospatial perception* refers to the ability to process and interpret visual information about the locations of objects in space. It underlies the ability to navigate in an environment, orient appropriately, and plan actions, such as reaching for objects. Visuospatial information can be either categorical or coordinate; categorical representations are abstract and propositional, whereas coordinate relations specify metric information on the relative location and distance of objects (Ruggiero et al., 2012; van der Ham and Borst, 2011) (also *see* Human Spatial Orientation, Neural Basis of, Visual Perception, Neural Basis of).

Peripersonal and Extrapersonal Space

Effective action planning and execution, such as when intending to reach for an object, requires an integrated neural representation of the body and of the space surrounding the body. *Peripersonal* (near) space is behaviorally defined as the space within the arm-reaching distance, whereas *extrapersonal* (far) space represents the area outside the arm-reaching distance. The coding of space as near and far is not only determined by the arm-reaching distance, but it is also dependent on how the brain represents the extension of the body space (Berti and Frassinetti, 2000). Closely associated with the notion of space representation are the findings from animal research on specialized visual neurons coded for the detection of near space (e.g., Iriki et al., 1996; Làdavas, 2002). In humans, a functionally homologous coding of peripersonal space is largely supported by behavioral studies, showing stronger visual–tactile interaction in near than far space in brain damaged patients (Brozzoli et al., 2006) and healthy individuals (see review by Macaluso and Maravita, 2010).

One line of research that has tested the perceived boundaries of peri- and extrapersonal space is the examination of tool use. There is a general consensus from research that a tool extends an individual's peripersonal space. Complementing this modulation is a 'remapping' of extrapersonal to peripersonal space. For example, Iriki et al. (1996) found neurons in the intraparietal sulcus of monkeys that fired when a raisin was presented within arm's reach but not beyond. The monkeys were then taught to reach with a rake, which extended their reach. The so-called 'reachability neurons' adapted to this change and responded to raisins that were presented further away but within reach with the rake. This research suggests that there exists visual neurons that code for what is within reach and that these neurons adapt to changes in reachability resulting from tool use. This general finding of remapping of far space as near space via tool use has also been demonstrated

with healthy adults and with patients showing spatial neglect (e.g., Cardinali et al., 2009; Neppi-Mòdona et al., 2007).

Space as Represented in Visual Frames of Reference

Egocentric and Allocentric Frames

In an excellent review by Wang (2012), the writer notes that the issue of reference frames is central to our understanding of spatial representations. Research findings are clear that there is not a single, explicit, topographic representation of space suitable for incorporating every kind of sensory input and generating every kind of motor output. On the contrary, evidence points to multiple representations of space, in a variety of coordinate frames, and linked to separate output systems designed to guide specific motor effectors.

The particular representation of space in use at any time depends on the task the individual is trying to perform. Spatial locations of objects in the surrounding environment are not only perceived based on an observer-centered (egocentric) coordinate, but also on an object-centered (allocentric) coordinate. For example, if you were to draw out a route for a hiking trip on a map, the route would be in the coordinates of the map, the piece of paper. If you were then going to walk along that route, you would have to begin by locating your current position within that coordinate frame and constructing a representation of the route with respect to your starting point. The first map-based representation is an example of an *allocentric representation* (framework), in which locations are represented in reference frames extrinsic to the observer. Allocentric representations include those centered on the object(s) of interest (*object-centered*) and those in environmental (room-centered or world-centered) coordinates.

The second representation, the one in the coordinates of the hiker's current position, is an example of an *egocentric representation*, in which locations are represented relative to the observer. Egocentric representations include those in eye-centered, head-centered, hand-centered, and body-centered coordinates. Most scientists would agree that multiple reference frames can be activated simultaneously when performing action tasks. For example, when reaching, allocentric cues are used to code specific characteristics of the object (e.g., shape, size, and location) and its surroundings. Then using an egocentric frame of reference the individual maps his or her body including the effector (hand) information with that of the reaching object.

Visual Processing Streams

Human brain imaging studies confirm that different cortical regions are active when participants process ego- or allocentric information. It has been proposed that egocentric cues associated with intended action are processed 'primarily' in dorsal stream brain areas, whereas allocentric representations are found mainly along the ventral processing stream. Moreover, specific propositions of the two-visual-system hypothesis (visual-for-perception and vision-for-action; Goodale et al., 2005) and behavioral data support the idea that for estimation judgments (as with reaching actions), the dorsal stream via egocentric reference is 'metrically' more accurate than the ventral stream (allocentric reference). Recent work also supports the idea that each hemisphere preferentially processes and integrates contralateral egocentric and allocentric stimuli (Zhou et al., 2012).

It should be acknowledged that, although the consensus of research leads to the notion that the two visual pathways have distinct roles, for action process, the two systems are not hermetically sealed from one another – perception and action are intimately linked. "After all, many actions, which are mediated by mechanisms in the dorsal stream, are conditional upon the presence of complex stimuli that can be interpreted only by mechanisms in the ventral perceptual stream" (Goodale et al., 2005: p. 274).

Moreover, the perception and action streams are speculated to operate under very different temporal constraints. That is, real-time (no-delay) movements depend on pathways from the early visual areas via relatively encapsulated visuomotor mechanisms in the dorsal stream. These dedicated visuomotor mechanisms, together with motor centers in the premotor cortex and brainstem, compute the absolute metrics of the target object and its position in the egocentric coordinates of the effector used to perform the action. In contrast, it is suggested that memory-driven actions make use of a perceptual representation of the target object generated by the ventral stream. Research testing the temporal aspects of the visual systems is supportive (Graham et al., 1998; Hu et al., 1999). Furthermore, extensive neuroimaging and neurophysiology work is supportive of the separation of the two streams (e.g., Cohen et al., 2009) (*see* Visual Streams: Dorsal and Ventral; Visual Perception, Neural Basis of).

Impairments Associated with Spatial Perception

Much of our knowledge about the neural basis of spatial perception comes from observations in patients with spatial deficits following brain damage. These include a wide range of perceptual and motor deficits, such as: poor localization of visual, auditory, or tactile stimuli; inability to determine visual or tactile line orientation; impaired performance on mazes; impairment on tests of mental spatial transformations; right–left confusion; poor drawing; impaired eye movements to points in space; misreaching; defective locomotion in space; and amnesia for routes and locations. As can be seen from this partial list, spatial behavior involves many kinds of skills and, not surprisingly, a number of brain regions have been implicated in spatial perception and performance. Broadly speaking, the parietal lobe is responsible for spatial perception and representation of immediate extrapersonal space, while temporal and parahippocampal cortices are more involved in topographic memory and navigation (*see* Navigation in Virtual Space: Psychological and Neural Aspects). The frontal lobe receives input from both parietal and temporal cortex and is responsible for generating actions.

An important point about deficits in spatial perception is that they are far more common after right hemisphere damage than left. While patients with left hemisphere damage may also exhibit spatial deficits, it is clear that the right hemisphere in humans has a superordinate role in spatial processing and behavior (Heilman et al., 1985). Two kinds of spatial deficits

following brain damage are particularly illuminating. First, a common sensorimotor deficit following parietal lobe damage is a difficulty in using visual information to guide arm movements, referred to as optic ataxia. Patients with optic ataxia have difficulty with everyday tasks that require accurate reaching under visual guidance, such as using a knife and fork. They both misdirect the hand and misorient it with respect to the object, and are most impaired when using the contralesional hand to reach for an object in the contralesional half of space (*see* Visual Streams: Dorsal and Ventral).

A second, classic disorder of spatial perception in humans is the tendency to ignore one half of space, called hemispatial neglect (*see* Hemispatial Neglect, Neural Basis of). The most common form of neglect arises from damage to the right parietal lobe and is manifested as a failure to detect objects in the left half of space. Neglect is more than just a visual deficit, however. It can occur separately or jointly across many sensory modalities. Moreover, neglect occurs with respect to many different spatial reference frames. A patient with right parietal lobe damage typically neglects objects on the left but left may be defined with respect to the body, or the line of sight, or with respect to an attended object. Further, this neglect is dynamic, changing from moment to moment with changes in body posture and task demands (Behrmann, 2000). Neglect is apparent even in the purely conceptual realm of internal images. Patients exhibit neglect when asked to imagine a familiar scene, such as a city square, and describe the buildings in it. The portion of space that is neglected changes when individuals are asked to imagine the scene from a different viewpoint. As this example illustrates, neglect can occur with respect to an internal image constructed by the individual. Patients with neglect show evidence of using multiple reference frames, just as intact individuals do.

One of the lesser-known disorders associated with difficulty with visuospatial tasks including spatial navigation is Williams syndrome. Recent work by Bernandino et al. (2013) found that these individuals also had significant impairment in making egocentric and allocentric spatial judgments.

Neural Aspects

Parietal Neurons Encode Spatial Information in Multiple Reference Frames

The standard approach for investigating the role of parietal neurons in spatial perception is to record electrical activity from individual neurons while the monkey performs a spatial task. Because brain tissue itself has no sensory receptors, fine microelectrodes can be introduced into the brain without disturbing the animal's performance. By recording neural responses during carefully designed tasks, neural activity can be related directly to the sensory and representational processes that underlie spatial behavior. The general conclusion from these studies is that the function of parietal cortex is to transform spatial information from sensory coordinates into the motor coordinates that are necessary for the guidance of action (Andersen et al., 1997; Colby and Goldberg, 1999) (*see* Human Spatial Orientation, Neural Basis of) (*see* Parietal Lobe).

Head-centered spatial representation in the ventral intraparietal area (area VIP). The area VIP is located in the floor of the intraparietal sulcus, where inputs from high-order visual and somatosensory cortex converge. In the visual domain, VIP neurons are characterized by direction and speed selectivity, and thus resemble neurons in other dorsal stream visual areas that process stimulus motion (*see* Neural Representation of Direction (Head Direction Cells)).

In the somatosensory domain, these same neurons respond to light touch on the head and face. The somatosensory and visual receptive fields of individual neurons exhibit strong spatial correspondence: they match in location, in size, and even in their preferred direction of motion. The existence of spatially matched receptive fields raises an interesting question: what happens when the eyes move away from primary position? If the visual receptive fields were simply retinotopic, they would have to move in space when the eyes do and so would no longer match the location of the somatosensory receptive field. Instead, for some VIP neurons, the visual receptive field moves to a new location on the retina when the eyes move away from the straight-ahead position. For example, a neuron that has a somatosensory receptive field near the mouth and responds best to a visual stimulus moving toward the mouth will continue to respond to that trajectory of motion regardless of where the monkey is looking. These neurons have head-centered receptive fields; they respond to stimulation of a certain portion of the skin surface and to the visual stimulus aligned with it, no matter what part of the retina is activated. Neurons in area VIP send projections to the region of premotor cortex that generates head movements. Area VIP neurons thus contribute to the visual guidance of head movements and may play a special role in hand, eye, and mouth coordination. They operate in a head-centered reference frame in order to generate appropriate signals for a particular motor effector system, namely that which controls head movements.

Eye-centered spatial representation in the lateral intraparietal area (area LIP). In contrast to area VIP, neurons in area LIP construct an eye-centered spatial representation. Individual neurons become active when a salient event occurs at the location of the receptive field. This can be a sensory event, such as the onset of a visual or auditory stimulus, or a motor event, such as a saccade toward the receptive field, or even a cognitive event, such as the expectation that a stimulus is about to appear, or the memory that one has recently appeared. The level of response reflects the degree to which attention has been allocated to the site of the receptive field (Colby et al., 1995).

Again, as we saw for area VIP, the animal's ability to make eye movements raises an interesting question about spatial representation. Neural representations of space are maintained over time, and the brain must solve the problem of how to update these representations when a receptor surface moves. With each eye movement, every object in our surroundings activates a new set of retinal neurons. Despite this constant change, we perceive the world as stable. Area LIP neurons contribute to this perceptual stability by using information about the metrics of the eye movement to update their spatial representation of salient locations (Duhamel et al., 1992). For example, LIP neurons are activated when the monkey makes an eye movement that brings a previously illuminated screen location into their receptive field. These neurons respond to the

memory trace of the earlier stimulus: no stimulus is ever physically present in the receptive field, either before or after the saccade. The proposed explanation for this surprising finding is that the memory trace of the stimulus is updated at the time of the saccade. Before the saccade, while the monkey is looking straight ahead, the onset of the stimulus activates a set of LIP neurons whose receptive fields encompass the stimulated screen location, and they continue to respond after the stimulus is extinguished, maintaining a memory trace of the stimulus. At the time of the saccade, a corollary discharge, or copy of the eye movement command, containing information about the metrics of the saccade, arrives in parietal cortex. This corollary discharge causes the active LIP neurons to transmit their signals to the new set of LIP neurons whose receptive fields will encompass the stimulated screen location after the saccade. The representation of the stimulated location is thus dynamically updated from the coordinates of the initial eye position to the coordinates of the final eye position. The significance of this observation is in what it reveals about spatial representation in area LIP. It demonstrates that the representation is dynamic and is always centered on the current position of the fovea.

Instead of creating a spatial representation that is in purely retinotopic (sensory) coordinates, tied exclusively to the specific neurons initially activated by the stimulus, area LIP constructs a representation in eye-centered (motor) coordinates. The distinction is a subtle one but critical for the ability to generate accurate spatial behavior. By representing visual information in eye-centered coordinates, area LIP neurons tell the monkey not just where the stimulus was on the retina when it first appeared but also where it would be now if it were still visible. The result is that the monkey always has accurate spatial information with which to program an eye movement toward a real or remembered target. The transformation from sensory to motor coordinates puts the visual information in its most immediately useful form. Compared to a head-centered or world-centered representation, an eye-centered representation has the significant advantage that it is already in the coordinates of the effector system that will be used to acquire the target. Humans with unilateral parietal lobe damage fail on an eye movement task that requires an eye-centered representation of a remembered target position. This failure presumably reflects an impairment of the updating mechanism in parietal cortex.

In sum, posterior parietal cortex plays a critical role in spatial perception and representation. Physiological studies in monkeys show that parietal neurons represent spatial locations relative to multiple reference frames, including those centered on the head and the eye. Individual neurons (in area VIP) combine spatial information across different sensory modalities, and specific spatial reference frames are constructed by combining sensory and motor signals (in area LIP). In accord with the physiology, human neuropsychological studies show that neglect can be expressed with respect to several different reference frames.

Frontal Lobe Mechanisms of Spatial Representation

The parietal lobe transforms sensory representations of attended objects into the motor coordinate frames most appropriate for action. They do not actually generate those actions. Dorsal stream outputs to frontal cortex provide the sensory basis, in the correct spatial framework, for producing specific motor outputs. The following sections describe specific spatial representations found in three regions of frontal cortex.

Neurons in premotor cortex have head-centered and hand-centered visual receptive fields. Two different forms of spatially organized visual responsiveness have been described in ventral premotor cortex. First, in subdivisions representing facial movements, neurons respond to visual stimuli at specific locations relative to the head, much like those described above in area VIP. These neurons have been characterized by recording activity while objects approach the monkey's head along various trajectories. The preferred trajectory is constant with respect to the head, and is not affected by changes in eye position (Fogassi et al., 1996). This specific zone of premotor cortex receives inputs from area VIP, and uses the same form of spatial representation. In both cases, stimuli are represented in the motor coordinate frame that would be most useful for acquiring or avoiding stimuli near the face by means of a head movement.

A different kind of spatial representation has been observed in subdivisions of premotor cortex involved in generating arm movements. Here, neurons respond to visual stimuli presented in the vicinity of the hand. When the hand moves to a new location, the visual receptive field also moves with it. Moreover, the visual receptive field remains fixed to the hand regardless of where the monkey is looking, suggesting the existence of a hand-centered representation (Graziano et al., 1994). A fascinating observation indicates that some neurons in this area are capable of even more abstract forms of representation. Rizzolatti and coworkers have described neurons in premotor cortex that are activated both when the monkey grasps an object, such as a raisin, and when the monkey observes the experimenter performing the same action (Gallese et al., 1996). These 'mirror' neurons encode not just the monkey's own motor actions but also the meaning of actions performed by others (*see* Premotor Cortex).

Object-centered spatial representation in the supplementary eye field (SEF). Actions are directed toward objects in the environment and toward specific locations on an object. Picking up your coffee cup requires that you locate both the cup in egocentric space and the handle in relation to the cup. The spatial reference frame that guides such movements is not limited to the egocentric representations described above. Evidence from the SEF demonstrates that single neurons can encode movement direction relative to the object itself (Olson and Gettner, 1995). The SEF is a division of premotor cortex with attentional and oculomotor functions. Neurons here fire before and during saccades. In monkeys that are trained to make eye movements to particular locations on an object, SEF neurons exhibit a unique form of spatial selectivity: they encode the direction of the impending eye movement as defined relative to an object-centered reference frame. For example, a given neuron may fire when the monkey looks toward the right end of a bar placed at any of several different locations on the screen, regardless of whether the eye movement itself is a rightward or leftward saccade. Moreover, the same neuron will fail to respond when the monkey makes a physically identical eye movement toward the left end of the

bar stimulus. This striking result indicates that single neurons can make use of quite abstract spatial reference frames. Object-centered spatial information could potentially guide arm movements as well as eye movements. Moreover, neuropsychological evidence indicates that an object-centered reference frame can be used to direct attention: some patients exhibit object-centered neglect after parietal lobe damage (Behrmann, 2000). Parietal lobe lesions in monkeys likewise produce impairments on tasks that require an object-centered spatial representation (*see* Neural Representations of Objects).

In sum, behavioral and neuropsychological studies indicate that we make use of multiple spatial representations in the perception of action space. Neurophysiological studies are beginning to uncover the neural mechanisms underlying the construction of these egocentric and allocentric spatial representations.

Performance: Anthropological Aspects

Felicia Hughes-Freeland, London University, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Anthropological approaches to performance include the analysis of behavior in social interactions; structured movement and speech language in rituals, acting, artistry, and aesthetics in staged theatrical performances; public events and their mediation; and political symbolism. Anthropologists use performance heuristically to understand social and cultural practices, drawing on concepts from ritual analysis, sociolinguistics, and philosophy. Key questions concern the relationship between text and performance, problems presented by the illusory aspects of performance in Western traditions for understanding social realities, and how to conceptualize the relationship between performance and ritual.

In anthropology, performance is a concept used to analyze a distinctive event or aspects of behavior and identity in all kinds of social contexts and situations. Performance was subsumed into ritual until the concepts of dramaturgical models were developed in the United States by Erving Goffman and led to the concept of 'cultural performances.' Two members of the British 'Manchester School,' Victor Turner and Abner Cohen, were influential in promoting performance as a means to understand the expressive and political aspects of social life. Communicative performativity developed in sociolinguistics has also been influential and has also shaped Judith Butler's account of gender as performative, which in turn has influenced anthropological thinking. Performance has produced more embodied forms of research, and Turner's theory in particular has stimulated interdisciplinary and intercultural dramatic projects. Anthropologists also produce in-depth ethnographic studies of performance to better understand the social processes of community building in religious and secular contexts, politics, resistance, conflict resolution, healing, creativity, and aesthetics. The key problem remains the question of boundaries. Is performance a discrete category of behavior or a fundamental aspect of all behavior? Is performance fundamentally deceitful? Is it determined by preexistent scripts and texts, or is it creative and emergent? Is it even applicable or relevant cross-culturally? What, if anything, does 'performativity' add to an account of social action? Anthropology uses performance to understand the varieties of human imagination and artistry in a wide range of different contexts, latterly including tourism and heritage. In the future, it is likely to be applied to the social engagement in the fields of information communication and technology and to understanding any form of professional practice, including medicine, law, finance, and education.

Anthropologists apply the concept of performance to distinctive events or aspects of behavior to contribute to the understanding of human behavior in any social context. These range from the most extraordinary and stylized forms of human behavior to the fundamental routines of everyday life, and address different areas of specialized professionalism and expertise, in ritual, commercial, economic, medical, technological, dramatic, artistic, creative, and sportive spheres. Initially driven by a theoretical concern with social function and meaning, contemporary research uses the performance concept to address issues of identity and the relationship between performance, self, researcher, time, and place, explicitly in relation to ritual, theater, and cultural politics, and implicitly in general ethnographic analysis.

Development of the Concept

Performance as an anthropological concept developed after the 1950s. Previously, anthropologists subsumed performance into the analysis of ritual, although researchers such as Gregory Bateson and Terence Ranger were already highlighting its analytical and empirical significance. British social anthropology had built its reputation as a science of total functioning systems and structures centered on kinship networks, and embodied forms of human expression, such as acting or dancing in theatrical and commercial venues, were mostly considered marginal to the discipline. By the mid-1960s, the broader humanist concepts of culture that characterized European and American anthropology gave the concept of performance a more central role in both social and cultural anthropological analyses.

The American sociologist Erving Goffman developed a model in which social interaction was explicable as acts and performances: "The world, in truth, is a wedding," he declared (Goffman, 1956: p. 23), having defined performance as "all of the activity of a given participant on a given occasion which serves to influence in any way any of the other participants" (1956: p. 8). Goffman coined the phrase 'impression management' and demonstrated the centrality of etiquette, tact, evasion, and white lies in micro-interactions. He employed theatrical metaphors to explain different aspects of behavioral presentation and 'multiple versions of reality.' All behavior occurs in stage-like social contexts: the public face of social behavior is 'frontstage' and more informal interactions are characterized as 'backstage.' This model was intended as a fifth perspective to complement existing technical, political, structural, and cultural analyses, subsequently integrated into his work on frame analysis. His dramaturgical and transactional vision remains influential in anthropological analyses of social interaction.

Milton Singer, Dell Hymes, Clifford Geertz, and Victor Turner have also shaped the ways in which anthropologists use

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12127-0

performance notions metaphorically to explain social action as 'cultural performance,' a complex system of symbolic and meaningful behavior that produces an ordered understanding of the world. Performance in these terms is not limited to representation but is an active and creative precondition for social life.

Victor Turner's work has been particularly influential on current uses of performance. Turner's approach is collectivist in contrast to Goffman's individualism; he moved from a functionalist study of ritual to cultural performance models and finally to theatrical performance itself. Yet performance was never separated completely from ritual, defined as a "transformative performance revealing major classifications, categories, and contradictions of cultural process" (Ronald L. Grimes, cited in Turner, 1987: p. 75). Turner's theory of ritual can be summed up by three key explanatory concepts. 'Ritual process' consists of three phases, separation, transition or liminality, and reintegration. Conceived by the Dutch structural anthropologist Van Gennep in the early twentieth century as a universal theory to explain rites of passage, Turner applied it to male initiation rites among the Ndembu. In this ethnographic study he also developed the second concept, 'social drama,' which explain social conflicts as having a threefold narrative dramatic structure – problem, confrontation, resolution – with people's actions being determined by their 'roles.' Thirdly, after having been influenced by Gluckman's functionalist theory that conflict ultimately gives way to harmony, Turner developed the argument that ritual action has the potential to release humans from the determining structure of their everyday life into a creative and liberating 'anti-structure,' or 'communitas.' This was the liminal phase of the ritual process that contrasted with the structure of everyday life. Before his untimely death in 1983, Turner extended liminality beyond the process of a specific ritual event and reconceptualized it as 'liminoid' to describe artistry and creativity in society, including theatrical performances, such as Noh in Japan (Turner, 1987: pp. 99–122). In this way, his conceptual framework came to merge the borders between initiation rituals and social events such as carnivals, films, and spectacles into cultural performances (Turner, 1987: pp. 21–74).

Turner has been one of the most widely influential of Max Gluckman's Manchester School of anthropology, partly because he worked in the United States. Other anthropologists of this background have also produced actor-centered transactional and conflict models using performance perspectives on more political topics, often drawing on Marxist theory. In his study of London's Notting Hill Carnival, Abner Cohen (1993: p. ix) reaffirms his interest in performance as part of a wider analysis of the relationship between cultural forms and political formations. Performance in political symbolism is interesting because it expresses the contradictions between the two dimensions of social interaction: the unintentional and moral nature of cultural action, and the amoral self-interest of political action (Cohen, 1993: p. 8). Cohen's work is recognized for highlighting the ritual dimension of political systems in general, but it has also influenced the analysis of performance as a political tool in postcolonial societies dominated by processes of retribalization and issues of ethnic identity; it is also relevant to the analysis of multiculturalism and cultural politics.

Other salient influences have come from sociolinguistics and linguistic anthropology. Theories that characterized communication as performative as well as informative were inspired by the Russian linguist Roman Jakobson's concept of 'poetic function' – "the way in which a communication is carried out" (Bauman, 1986: p. 3) – and J.L. Austin and John Searle's attention to performativity in speech act theory. For instance, Richard Bauman (1986) has analyzed American folk narratives using a framework of story, performance, and event, and has greatly influenced research into oral tradition and oratory as performance. This specialized use of performance has also been very influential in establishing the performative dimensions of other kinds of communication, particularly in the study of competence and play. Anthropologists such as James Fernandez have also developed communicative approaches to the performance of metaphor in various social contexts. Such work on verbal performance has influenced general theories of performance in human behavior. The concept of performativity has also shaped Judith Butler's influential analysis of gender, which in turn has fed back into some anthropological accounts of the performance of gender and sexuality in everyday life.

Methodological Innovations

Anthropology has always been a discipline that attracts people with an experience of life outside academe, and the 1980s saw the emergence of performer-anthropologists, scholars who had previously worked on the stage professionally as dancers and actors. Anthropologists who have not been professional actors or dancers may choose to include training in performance as part of their research, using their bodies to explore familiar or unfamiliar techniques self-consciously by learning alongside aspiring professionals and experts. Increasing attention is being paid to different performance skills and genres, not simply as objects of study but also methodologically. This has contributed to critiques of Cartesian dualism in accounts of human action and the long-overdue recognition of the importance of embodied behavior and what Marcel Mauss conceptualized in the 1930s as 'techniques of the body.'

Turner's Legacy in Theater

The anthropological interest in ritual that Turner extended to theater resulted in an intellectual collaboration with Richard Schechner, a theater director and theorist of comparative performance who researches both practically and theoretically the common foundation of human creativity in ritual and theater. It is largely through him that Turner's last writings on performances as liminoid phenomena were published, promoting an interest in theatrical and other forms of contemporary performance in performance studies and cultural studies as well as anthropology. Indeed, in his preface to the book *Between Theatre and Anthropology*, Turner wrote that Schechner "might just be the catalyst anthropologists need to get them thinking about what Dilthey [the German hermeneutic philosopher] called 'lived-through experience'" (Turner in Schechner, 1985: p. xii; see also Turner, 1987: pp. 84–90).

The continuum between performance with ritual efficacy and theatrical performance rests on the theory that performance is 'restored behavior,' strips of behavior with 'a life of their own,' which can be rearranged or reconstructed independently of the various causal systems that brought them into existence (Schechner, 1985: p. 35). The 'machine' for the restoration of behavior is the liminal "workshop-rehearsal process … [which] is the same in theater as in ritual," as both function to restore behavior (Schechner, 1985: p. 113). Schechner has been a dominant theorizer of performance drawing on anthropological interests, but other theater director-researchers, from James Brandon to John Emigh and Phillip Zarrilli, also produce work informed by an anthropological sensitivity to fundamental cultural differences that provides inspiration for anthropologists who do research on performance in different societies across the world.

The encounter between theater and anthropology became a well-established interdisciplinary field in the United States during the 1980s and in the United Kingdom and Europe a decade later. In 1980, Eugenio Barba founded the International School of Theatre Anthropology; "Turner did for anthropology what Barba is doing for theater," declared Schechner (1985: p. 30; see also p. 257). Theater anthropology is not the study of performative phenomena by anthropologists, but of pre-expressive behavior by theater professionals in organized performance situations. It operates collaboratively with performers from societies with long-established theatrical traditions, including Japan, India, Indonesia, and Brazil, and in some cases with anthropologists. In 1990, Kirsten Hastrup's life story was 'restored' (to use Schechner's term) by Barba's Odin Teatret as a drama, *Talabot* (Hastrup, 2004: pp. 35–36). In the past decade, Performance Studies has become stronger with funding since the recognition of practice-based research for funding. It is also the case that performance practitioners who once might have become anthropologists are more likely to turn to performance studies.

Aesthetics and Creativity

Performer-anthropologists are often inspired by Turner's approach, including the former ballet dancer Anya Peterson Royce. She analyzes performance as 'the performing arts' cross-culturally to develop a general explanatory model of virtuosity and artistry based on "aesthetic principles that are common across genres, space and time" (Royce, 2004: p. 237). This approach brings together various dance forms (including Tewa ritual dances), mime, and cello music, and challenges the more common anthropological caution about aesthetics as a cross-cultural category. This study is among a number that are extending the range of embodied practices analyzed as performance by anthropologists, including the martial arts, performance art (see multimedia annex), literary writers, and others in interdisciplinary research in sports science.

More generally, anthropologists analyze creativity as a social phenomenon that is subject to structural constraints, both inside and outside the domain of the performing arts, and apply their theory to cross-cultural creative performance collaborations. In the twenty-first century, cross-cultural performances have increasingly been analyzed with reference to hybridity, most recently in dance studies in Asia. Anthropologists have critiqued hybridity because it reintroduces cultural reification by implying an authenticity or cultural purity in the elements that are combined and conceals substantial power differentials, including abuses of intellectual property. This critical awareness of hybridity may impact on performer creativity and feed back into anthropological analyses of performance. Anthropological approaches can also examine conflicts about ownership that are more frequent in transcultural theatrical productions.

Theater and Social Action

Anthropological analyses and uses of performance are not limited to the technicalities or aesthetics in theater and acting. Anthropologists also explore theoretical questions about social action through the analysis of stage acting in theatrical contexts. Johannes Fabian's pioneering ethnography with the theatrical Troupe Mufwankolo in Shaba, Zaire, marked a shift from "informative to performative ethnography" and a more "dialogical" form of anthropological practice (1990: pp. 5, 19). Performance is approached like an ethnography of speaking, not as the enactment of a script but by "giving form to … making, fashioning, creating" (1990: pp. 11–13). Fabian explored local concepts of power through drama and television, and demonstrated that performance must not focus on the aesthetic at the expense of power (1990: p. 17). Fabian is critical of the application of performance in a theatrical sense to societies with a different understanding of theater (1990: p. 14), and the conflation of performance and a general model of action, but he recognizes the real, not ritualized, redressive power of performance as social praxis (Fabian, 1990: p. 286).

Fabian has inspired a study of theatrical actors by Kirsten Hastrup, who explores the implications of action to understand human agency in general:

> Theatre is no metaphor for social life in the present context it *is* social life … To study theatre, therefore, is to study human actions in the real world as experienced by agents who are their own centers of attention to the world. (Hastrup, 2004: p. 19, emphasis in the original)

Building on longstanding interests in theater and philosophies of human action and knowledge as a reflexive situated practice validated by experience, Hastrup interviews Shakespearean actors about their experiences of performing in productions on stage and screen. Her account of the plays and their performance reveal an unfolding and mysterious world shaped by the power of language: "As thoughts in action words do change the world; nothing is ever quite the same after the words have been spoken" (2004: p. 319). Separating agency from intentionality, and noting that our actions are followed by a long coming to terms of how they bear on actions that affect others, Hastrup plots a schema for theater to explain the sociality of individuals (2004: pp. 322–331). This approach to individual human experience and actions through theater is very different from the rational calculation of Goffman's social actors through dramaturgical metaphors, and raises different implications for thinking about individual human choice and agency.

In considering anthropological approaches to the relationship between theater and action, a brief comment about gender identity and staged performances is necessary. Since James Peacock's (1968) early analysis of male-to-female cross-dressing in popular Javanese *ludruk* theater, accounts of theatrical cross-dressing have been complicated by Butler's theoretical analysis of gender-as-performance, where performance refers to action and identity. When theatrical gendering is discussed, for instance in relation to cross-dressing, there is a risk of performative skill being conflated with an expression of sexual preference. Anthropological approaches to cross-gendered stage performances are now engaging more rigorously with cultural and historical factors in cross-cultural analyses that recognize specific approaches to skillful theatrical gender impersonations by women as well as men (see multimedia annexes).

Ritual, Performance, and Media

Anthropological analyses of performance in ritual contexts continue to produce conceptually innovative research. For example, studies of performance within the social processes of healing have combined transactional and conflict models with analyses of the aesthetic and expressive dimensions of performance in the face of political repression or disenfranchisement. Michael Taussig (1993) invokes Marx and the Frankfurt School to explore mimetic behavior that lies at the heart of shamanic healing and social imagery, simultaneously representing and falsifying the world, and demonstrates how irrationality is being performed at the heart of the everyday. 'Mimetic excess' creates 'reflexive awareness,' which makes connections between history, make-believe, and otherness. More radically, anthropologists have applied healing processes from other cultures to help the sick at heart in their own societies by means of "a theatre model of dramatherapy" (Jennings, 1995: p. xxvii). While Aristotle's concept of catharsis may seem universal, different theaters produce forms of what Sue Jennings (1995: p. 185) calls 'abandonment,' and these vary greatly in their effects and forms of control. Ultimately it is this variation that must concern the anthropologist, not a universal explanation that is generalized out of one particular cultural perspective. Such explorations are a reminder of how the study of ritual performance promotes an understanding of how humans express their possession and dispossession, and of the permeability of the boundary between ritual performance and artistic performance.

Anthropological approaches to performance are shaped by whether the methodological approach is one that privileges analytical intersections or boundaries. As human interaction intensifies across time and space, anthropological approaches to performance have addressed the limits of dichotomizing 'everyday' vs 'ritual' realities in the complexity of contemporary life. Attention to media (television, film, and video) has opened up wider contexts for debates about performance being a specialized form of behavior or part of emergent everyday lives. The concept of performativity has been combined with Bell's definition of ritualization ("a way of acting that is designed to distinguish and privilege what is being done in comparison to other usually more quotidian, activities"), which could equally apply to performance, to question the division between ritual and everyday life, and to propose that ritual is not a genre of performance but that "performance in part constitutes ritual and ritualization" (Hughes-Freeland, 1998: pp. 3–6). The three domains were all deemed "in some sense virtual realities, mediated by technologies … in contradistinction to sensate everyday reality," although Goffman's penetration of everyday life by ritual undermines any fixed formulation (Hughes-Freeland, 1998: pp. 10–11). A consideration of these intersections affirmed that anthropologists achieve an understanding of their own categories through their encounter with different models, and that any convergences that arise will help to move forward debates about "the relationship of various expressions of imagination to other forms of life" (Hughes-Freeland, 1998: p. 15).

In the past decade, the analytical relationship between performance and ritual is being disentangled. This is due to a number of reasons. The concept of secular ritual made possible an exploration of intersections, but the term *ritual* is now being employed metaphorically across so many different domains that it risks losing analytical salience. For example, liminality is routinely applied to ceremonial events covered extensively by the print and broadcast media. In some approaches, technological mediation replaces ritual with spectacle, while in others, television broadcasts extend the ritual into the secular domain. The question to ask now is whether there is a limit to which the ritual process can be stretched across time and space (Hughes-Freeland, 2006: pp. 612–614). Just as ritual events may need to be distinguished from media ones, the relationship of performance to ritual, and the relationship of both to action, is also being reevaluated as a central issue (see following).

Performance and Cultural Politics

Some of the previously discussed approaches have included the political dimension of performance, but there is also evidence of Abner Cohen's somewhat neglected approach (outside the domain of African studies) to political symbolism and ethnicity in studies of performance. This is illustrated in two ethnographic studies about Southeast Asian societies.

The first study explains how social and cultural values are embodied and enacted in everyday social interactions in Javanese court dance movement and aesthetics, and how these become transformed into official Indonesia culture (Hughes-Freeland, 2008). In this analysis, performance is caught up in the contradictions between the two dimensions of social interaction: the unintentional and moral nature of cultural action, and the amoral self-interest of political action (Cohen, 1993: p. 8). Classicized court dance is a form of social production that plays a symbolic and an instrumental role in the construction and continuation of local and national communities (2008: pp. 11–13). Cultural politics include court dance in the domain of official national culture but exclude other performances practices with ritual and healing powers. For example, *tayuban* dancing occurs at annual community events in certain highland villages in Java due to the support of the local leader. As part of the occasion, people bring their children and animals (represented by their tethering ropes) to be cured by the face powder of women singer-dancers that carry the power of the village spirit (Figure 1). A more

Figure 1 Female dancer in Java protects a baby with face powder (as in first edition).

political approach to performance is evident in other research into the relationship of embodiment as sensorial experience and citizenship.

Cohen's influence is more implicit in a second analysis of the dynamics of ethnicity and elitism in cultural politics in Chinese street opera in multicultural Singapore. Lee's (2009) cultural analysis begins with changes in the social organization and troupe membership following the first migrations from China in the 1840s. By the 1970s, Singaporean cultural politics was privileging amateur troupes that perform a few times a year, mostly in indoor theaters (2009: pp. 75–95). Meanwhile professional troupes, despite their decline after theater closures in the 1960s, perform almost daily at temple festivals (2009: pp. 117–137). These two forms of Chinese opera have distinct audiences and value systems that differ from Chinese opera performances for tourist audiences at Clarke Quay. These provide a Geertzian "metacommentary upon the role of cultural tradition and processes of modernization in Singapore … tourism and culture are constitutive of each other" (2009: p. 137). This ethnomusicological research is also informed by business studies, providing further evidence for the potential for interdisciplinary forms of contemporary social analysis of performance and cultural politics. The recognition of internal differentiation and heterogeneity of socio-aesthetic and social values within these anthropological approaches to performance run parallel to those of the French philosopher Jacques Rancière, who has lately become fashionable, but differ from him because his theories about aesthetics and power derive entirely from Western art and epistemology. Both these studies also address the way in which governments and performers respond to local and international tourism, another field for new analytical perspective on performance.

Place, Tourism, and Heritage

For the past 30 years, the analysis of performance in pilgrimage has created a link between ritual and tourism, but in the past decade, the 'topological' or 'topographic' turn in anthropology has produced new approaches to performance in relation to place and movement across space.

In anthropological accounts of tourism, performance applies to performances for tourists, and to tourism itself as a distinct sphere of action. Earlier accounts of tourism that privileged the gaze and spectatorship have been challenged by concepts from performance theory, and specific tourist behaviors are being analyzed as performances. This performative approach gives greater weight to participation as "a dynamic sense of embodied and performed, as well as visualized and textualized, engagement with places and tourist activities," and go "beyond the visual to performance" (Coleman and Crang, 2002: pp. 1, 11).

Approaches to mobility simultaneously generate a revived interest in place and in site specificity. Anthropologists also collaborate with archaeologists and art historians to research public interactions with heritage sites, as in Blain and Wallis's sacred sites project (see multimedia annex). Another recent framework for the practical exploration of performance in space, theater archaeology, developed in Wales by Pearson and Shanks, could potentially produce interesting new collaborative approaches to place and performance.

The interest in place and mobility is linked to the enormous field of heritage studies. Here, performance is discussed in relation to its classification by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) as intangible heritage. Critiques of the criteria for classifying cultural heritage have resulted in heritage researchers moving away from performance as event to performance as action. Smith and Waterton (2009: p. 291) note a common ambivalence about intangible heritage in "authorised heritage discourse," and provocatively suggest that all heritage is intangible. Heritage "is the performance and negotiation of identity, values, and a sense of place …. One of the key consequences of the heritage performance is the way in which it is used to legitimise and authorise identity" (Smith and Waterton, 2009: pp. 292–293). As performance itself involves these

processes of negotiation and legitimization, there is a theoretical complication here that needs to be untangled in the future. This is also an area in which anthropologists are researching conflicts about cultural ownership and the control of representation in performance.

Central Issues

Performance is productive both of individuals, with gendered, ethnic, or other specified markers of social identity, and of social formations of different scales. There has been a tendency to explore performance as ritual, or in theater, or in art, or to frame certain specialist behaviors, such as tourism, as performance. Exceptions are the concerns with the relationship between performance, action, and ritual. Performance is also integrated into wider ethnographic analysis, but in the past decade it has been subsumed by a range of theories and methods and has had a lower profile as a key anthropological concept, even as anthropological approaches to performance are being highlighted in sociology and 'performance geography.'

An important debate about performance is the extent to which human action is scripted or emergent. Is performance best understood as mimesis and imitation, or as *poesis*, creative, emergent, and transformative? In the 1980s, performance was addressed by linguistic anthropologists to counter textual approaches to oral traditions. This generated a reaction emphasizing performance in anthropology, and debates became polarized as performance models vs textual models, with a link to process models vs structural ones. One party stressed the determinacy of form; the other gave primacy to emergence, praxis, and experience. By the start of the twenty-first century this insight was recognized belatedly in the humanities (for instance, in Beyond Text, a research program funded by the British Arts and Humanities Research Council).

However, in anthropology there had already been doubts about the performative emphasis and the ensuing polarization between text and performance:

> performance theory provided wonderful conceptual tools for thinking about emergence …. [but] It offered inadequate resources for understanding how the fluid is consolidated, and why stunningly creative oral performers so often claim that their texts have never changed by so much as a syllable. (Barber, 2007: p. 29)

The necessary complement to performativity is entextualization, a concept developed by anthropologists working on performance in the 1990s (Kuipers, Urban, and Silverstein), because it allows an oral performance to be detached from the time and place of its enactment. It also explains how orally transmitted forms, as well as written ones, endure or 'stick' (Barber, 2007: pp. 28–31). This is one example of a reintegration of the relationship between text and performance, which are no longer necessarily mutually exclusive or oppositional, though there are variations in the analysis of script and enactment and how performances generate textual meanings (see multimedia annex).

This debate situates performance centrally within current polemics about anthropological knowledge and whether it should represent itself as operating within a system of models and rules or performatively and dialectically. Anthropologists still approach performance as being risky and interactive, rather than determined and predictable, using active and participatory models of spectatorship, not passive ones, on a continuum of general varieties of human interaction.

Another central concern is the cross-cultural application of performance, given its fictive theoretical foundations. Schieffelin (1998) has warned against exporting Western concepts to analyze other societies. Goffman's performance model draws on Western notions of theatrical performance in which illusion is central: theater is about make-believe, not real life. However, for Kaluli audiences at séance healings and the Gisalo ritual in Papua, New Guinea, the effects of performance are real, not illusory; audiences respond with real, not conventional, emotion. The anthropology of performance should move away from the representation of reality to the social construction of reality: "the concepts 'performance'/'performativity' have the potential to open a considerable domain for anthropological exploration of the way that cultures actively construct their realities" (Schieffelin, 1998: pp. 199–200). This resonates with approaches by Fabian and Hastrup that use different epistemological frameworks. Performativity in Goffman's account necessitates questioning what, if ever, is authentic action or representation, although a focus on experience and embodiment has moved analysis away from such questions – but they refuse to go away. Interestingly, it has recently been argued that Schechner's distinction between ritual and performance as a distinction between efficacy and instrumentality in contrast to entertainment suggests that, despite his association with Turner and his ritual theory, he is closer to Goffman (the ritual skeptic) than to Turner (the ritual enthusiast) because Schechner's emphasis is on the "fictive, contrived nature" of liminoid restored behavior (Grimes, 2012: pp. 32–34).

There have also been some challenges to the intersection between performance and ritual. Bruce Kapferer, formerly a proponent of performance in an analysis of healing and personhood inspired by G.H. Mead, has revised his performative approach to ritual, arguing that ritual is constituted by virtuality (from Langer to Deleuze and Guattari): "Insofar as ritual can be conceived as a technological virtualizing practice, a virtual reality machine, it is a device for entering into human actualities and is an opening and slicing into actuality" (Kapferer, 2006: p. 675). Ritual accommodates performance and mimesis, but should not be defined by them. This argument here is based on the premise that ritual performance is representational, but as most of the approaches to performance discussed here are nonrepresentational, this criticism may not result in ritual being uncoupled from performance. Kapferer's technical idiom is intriguing, but even more significantly it is the reminder that different orders of reality are socially constructed; there are a multiplicity of forms of experience that provide scope for further analytical differentiation.

A second challenge to the relationship between ritual and performance occurs in a recent statement by a pioneer of performance theory in ritual analysis. In a critique of the trajectory of 'cultural performances' within anthropology, including Turner's own contribution, Ronald L. Grimes stresses

that "*ritual* and *performance* are different only two children of the parent term, *action*. They have other siblings, such as *play*, *sport*, *dance* and *music* …. When speaking technically, I prefer to say that ritualists 'enact' rituals, whereas actors 'perform' plays" (Grimes, 2012: pp. 34–35, emphasis in the original). The differences between performance and ritual are not essential, but can be worked out using family resemblance theory (polythetic classifications), and with due recognition to "*degrees* of ritualization" (Grimes, 2012: p. 39). This qualification allows for a less categorical opposition between ritual and performance, but it is a warning against routinizing analytical hybrids such as performance-as-action or ritual-as-performance, and to be alert to dramaturgical metaphors coming into explanatory frameworks through the back door, and a tendency to use 'performing' as a synonym for a phrase involving certain kinds of action in contexts such as gender and tourism, for example. Grimes's challenge would also certainly require a revisiting of performativity, and an answer to a question that the late Raymond Firth once asked (at the ASA conference in Swansea in 1996): "Do we need performativity?"

More fundamentally 'ritual,' like 'theater' and 'performance,' should not be assumed to be culturally ubiquitous. As a path-breaking critic of the essentialization of dance as a category has recently observed, she researches 'structured movement' within ritual, but the viability of ritual itself as an analytical category is still being assessed through her ongoing comparative research (Kaeppler, 2010: p. 271). Once again, the anthropological impulse is to test, rather than to theorize a priori.

This heuristic attitude also applies to performance. It is important to specify whether performance is treated as universalizing meta-theory, a metaphor, event/action context, or a locally grounded concept. In anthropology, there are different strategies toward performance and its assessment, and these vary according to attitudes to concept formation and theoretical preferences. Some of the innovations noted previously appear to reassert boundaries and situate performance in empirical theatrical contexts: Zaire theater troupes, Shakespearean plays, Chinese street opera, or Javanese court dance. But they do this to explore broader social issues. By critically questioning the presuppositions supporting categorical oppositions implied in performance, such as pretense vs authenticity, and by going against the grain of their own cultural presuppositions, anthropologists are able to construct descriptions of alternative ways of seeing and being in the world, and to celebrate the diversity of human cultural experience despite its shared biophysical nature. Anthropologists in principle thus differ in their treatment of performance from those working in other disciplines, insofar as they recognize regional frames of reference and produce detailed ethnographic research. This may refer to what performers do and how they explain their work in contexts that nonanthropologists may identify as theatrical or staged; or it may refer to other contexts and events, or to the processes of everyday interactions.

Future Directions

Anthropologists have used performance as a means to understand social life, social interaction, and the social contexts for the formation and expression of human creativity. By avoiding definitions and using the performance concept in a heuristic manner, they are able to develop insights into the acquisition of competence, as general socialization or as training to acquire particular skills, and to further their understanding of social interactions and formations. In the future, it is to be hoped that they will be able to continue to do so.

By the end of the twentieth century, questions about function and meaning that had framed the anthropological project were being superseded by concerns with identity and experience.

Media and information and communication technologies facilitate virtual realities, and complicate the different ways in which performance may be transmitted and received, beyond the defined space–time continua of theater, ritual arena, or event. Anthropologists research all performance arenas, including cinema, television, and the Internet, and now Web 2.0, social media to the latest mobile mass communications, offer further permutations of sociality that would have been unimaginable 20 years ago. The proliferation of performance and ritual metaphors in the analysis of media events, for instance, has raised questions about analytical intersections, and some have asked for a rethinking of conceptual boundaries between action and performance as one of its other domains.

Visual technologies give access to all kinds of performance, rather than simply verbal accounts. Although these moving images are not pure imitations of the performances as they occur, it could be argued that the researcher is freer to respond directly to the performance than when reading about it. For example, Maya Deren's film of *vodun* possession in Haiti, *Divine Horsemen* (1947–51), and Jean Rouch's film of the *hauka* possession cult in Ghana in 1953, *Les Maîtres Fous* (*The Mad Masters*), presents images that language might fail to represent as convincingly real (see multimedia annex). Experimental ethnographic explorations of the relationship between embodied performance and text suggest innovative and exciting approaches to issues of analysis and representation in anthropology.

In the past decade, there has been a radical change in access to images of performance on YouTube and Vimeo, but the ethnographic context is not always clear, and such images can produce fragmentary impressions and endorse prejudice, rather than anthropologically founded understanding. The anthropological analysis of performance in cyberspace and the knowledge it produces is potentially valuable within the much wider field of transmission, learning, and social continuity. Performativity meanwhile continues to have relevance in the analysis of social media, particularly in relation to processes of self-invention and the creation of false identities. Important questions for anthropologists to examine concern the kinds of reality constructed in between public enactments, on the walls and pages of social media and in virtual worlds in cyberspace, and the relationships of these spheres of activity to off-line behavior.

The potential fields for the development of anthropological approaches to performance are numerous. The study of linguistic performance has already been employed in communication analyses in the field of artificial intelligence,

a development that extends to understandings of embodied performance. Some of the innovations discussed before will continue to develop. Performance will be part of anthropological engagements with public culture and issues of social relevance, such as migrant experiences, claims to cultural ownership, and the role of social media. The Occupy Movement has brought back performance to the streets as an expression of political dissent. This will add to the use of performance action in participatory methods and to applied theater in development and community projects. The anthropology of performance is among the most ostensibly humanist of the more recent subareas of anthropology, and its qualitative methodologies will be of value in balancing quantitative approaches in analyzing any form of professional practice, including medicine, law, finance, education, and the creative industries, in order to understand the processes that have come to give it the meaning of 'meeting targets' in neoliberal discourses.

Despite living in a globalized world, the requirement for national relevance in research is, to a certain extent, impeding attention to cultural diversity in performance, and less international research is being done away from the anthropologist's country of employment. An unintended consequence of this trend is for a new 'armchair anthropology' to be developing, in front of computer screens. To forestall the very real possibility of a return to a new ethnocentrism as a result of this lack of cross-cultural experience in research, it is crucial that in the immediate future, anthropologists continue to work against the grain of the new parochialism lurking behind the seeming borderlessness of information and communications technology (ICT), and to sustain a less culturally entrenched view of human performance activities. To achieve this, anthropologists need to engage in intracultural or cross-cultural performances to promote wider understanding about the different ways of acting human within the constraints of the group at whatever level and the challenges performance presents to those constraints which allow the expression of human nature in its different forms.

Abstract

Performance appraisal (PA) refers to the methods and processes used by organizations to assess the level of performance of their employees and to provide them with a feedback. This process can be used for both developmental and administrative purposes. The research on PA includes examination of the psychometric aspects of the appraisal tools, the cognitive process and the biases involved, and the social context. Although PA is an important tool for managing employees, managers, and workers are rarely satisfied with it. Therefore, clearly defining the purposes of the PA and addressing the employees' reactions are essential to the success of the PA.

Definition of Performance Appraisal

Performance appraisal (PA) plays a central role in managing human resources in organizations (e.g., Boswell and Boudreau, 2002; Cardy and Dobbins, 1994; Judge and Ferris, 1993). The term performance appraisal (or performance evaluation) refers to the methods and processes used by organizations to assess the level of performance of their employees. This process usually includes measuring employees' performance and providing them with feedback regarding the level and quality of their performance (DeNisi and Pritchard, 2006). The main goal of the PA in organizations is to improve employee performance (DeNisi and Pritchard, 2006; Murphy and Cleveland, 1991). This goal could be achieved through three possible mechanisms: (1) the information provided by the PA can be used for administrative decisions linking the evaluated performance to organizational rewards or punishments such as a pay raise, promotion, or discharge (Cleveland et al., 1989; Landy and Farr, 1980; Raynes, Gerhart, & Parks, 2005); (2) the PA process involves providing performance feedback (i.e., information regarding the level of performance) to the employees who were evaluated, allowing them to adjust their performance strategies to match the desired performance (e.g., Erez, 1977; Kluger and DeNisi, 1996; Locke and Latham, 2002); and (3) the PA is a process that raises employee awareness to the fact that they are being measured. As has been shown since the Hawthtorne studies (Roethlisberger and Dickson, 1939) and is expressed in the aphorism "what gets measured gets done," the mere fact of knowing that one is being observed or measured increases performance and fosters cooperative behavior (Bateson et al., 2006; Haley and Fessler, 2005; Keller and Pfattheicher, 2011). While the first and second mechanisms of PA have been widely explored, the third has received little attention in the PA literature.

Criteria for PA Effectiveness

Assuming that the main purpose of the PA process is to increase performance, an effective PA would be one that achieves this purpose. However, it is not as obvious as it seems to establish the criteria for effective PA that lead to performance improvement: Does effective PA mean that the scales in use are accurate and free of rater biases? Or does it mean that the workers accept the PA results and are willing to change their manners accordingly? While early research focused primarily on the accuracy of ratings as the only criterion for PA effectiveness, recent studies have suggested focusing on motivational aspects such as ratees' reactions to the PA (e.g., satisfaction, feedback acceptance). In order for workers to improve their performance following an appraisal, they must accept the appraisal rating and be willing to change their performance accordingly. Ensuring workers' reactions such as satisfaction, commitment, acceptance of the appraisal, and trust in management could help organizations achieve the primary PA purpose of improving performance (Keeping and Levy, 2000; DeNisi and Pritchard, 2006; Mayer and Davis, 1999). In order to yield positive reactions among ratees, the PA process should be perceived as reliable, accurate, and free of political interests on the one hand, and allow the ratee to participate in the process and express his or her voice on the other. The shift from measuring the accuracy of the appraisals to measuring the ratees' reactions and motivations reflects a significant change in the research of PA (Levy and Williams, 2004). This shift will be discussed in the following section.

Changes in the Focus of Performance Appraisal Literature

Until the 1980s, the focus in the PA literature was on measurement development and the psychometric characteristics of the different tools used to evaluate performance (Arvey and Murfey, 1998; Landy and Farr, 1980). Specifically, most research was concerned with improving these tools, constructing rating scales, and examining the advantages and disadvantages of different types of ratings. This psychometric tradition changed dramatically in the early 1980s when the focus of research shifted to the cognitive characteristics of the raters (e.g., Feldman, 1981; Landy and Farr, 1980). Drawing on social cognition and cognitive psychology, researchers began to explore how raters create impressions and judgments of their subordinates (Arvey and Murfey, 1998). The PA literature has become more concerned with attribution errors, categorizations, stereotyping, and other biases involved in information processing (e.g., DeNisi et al., 1984; Dobbins et al., 1988; Feldman, 1981).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.22034-5

Another historical change in the PA literature has occurred since the 1990s. At the beginning of the decade, several keynote reviews (e.g., Bretz et al., 1992; Ilgen et al., 1993; Murphy and Cleveland, 1991) argued that cognitive process models had failed to narrow the gap between research and practice, and since PA is an applied subject, there should be increased effort to make the research more applicative. The cognitive approach assumed that the cognitive process is universal and, therefore, the different content domains in which PAs practically occur (Ilgen et al., 1993) were overlooked. Researchers at this time suggested that in order to contribute to the practice of PA in organizations, it is important to understand the specific context in which an appraisal takes place, especially the social context (Levy and Williams, 2004). As the appraisal process takes place in a social context, it is, therefore, crucial to understand this context for appraisal success. The PA process is doomed to fail if the ratees perceive it as unfair or manipulative, even when the psychometric aspects of the process are valid (Cawley et al., 1998; Keeping and Levy, 2000; Levy and Williams, 2004). Some prominent components of the social context that influence the PA process will be reviewed further in this article, but first we introduce a key element in every PA system: feedback.

Performance Feedback

Providing employees with feedback regarding their performance is a common reality in most organizations. This type of feedback is defined as "actions taken by (an) external agent (s) to provide information regarding some aspect(s) of one's task performance" (Kluger and DeNisi, 1996: p. 255). This definition reflects the idea that feedback is 'information' or 'knowledge' delivered to an employee in order to make him or her aware of the level of their work outcomes. Performance feedback could serve as an important motivational source for workers if it is conducted effectively (Peiperl, 2001). Also, workers are interested in performance feedback in order to know how close they are to fulfilling their job assignments. However, giving (and receiving) feedback seems to be a challenging task. In the mid-1990s, Kluger and DeNisi (1996) published an extensive review and meta-analysis on the impact of feedback interventions. Their meta-analysis of feedback literature includes 131 articles and 607 feedback effects published between 1905 and 1996. Kluger and DeNisi found that in contrast to the common view that governed the feedback literature for nearly a hundred years, feedback does not always achieve its desired effect. Specifically, in more than a third (38%) of the studies reviewed, feedback was actually followed by a decrease in performance. Moreover, they found that the level of positivity or negativity of the feedback (i.e., feedback sign) does not explain why some feedback interventions were effective, while others were not. Lastly, the authors suggested and demonstrated that the level of the feedback (i.e., task details, task performance, and meta-level – the self) moderates the feedback–performance relationship. Specifically, effective feedback should help the receiver concentrate on the level of task performance, namely, the specific ways to improve his or her performance. Feedback often shifts the attention of the receiver from this level to a higher or a lower level; for example, the feedback could shift receiver attention to a higher level of the self (e.g., what this feedback says about me), or to a lower level of the task details (e.g., how I am holding my hands while teaching). The authors argued that feedback that either shifts attention to too high or too low a level, may be ineffective. This is mainly because people's cognitive resources are limited and if too much attention is invested on specific details or even worse, in one's self, there may not be enough resources available for performance improvement.

Recently, it was suggested (Van Dijk and Kluger, 2004, 2011) that the distinction between promotion and prevention goals or tasks (Higgins, 1997, 1998) could help defining the situations under which feedback will be effective. Specifically, tasks that are performed to satisfy one's wishes and aspirations (promotion tasks) benefit from positive feedback, while tasks performed to meet duties and obligations benefit from negative feedback. Practically, it suggests that one size does not fit all; thus, managers should tailor the feedback according to worker and task characteristics.

In light of the complexity of executing effective feedback processes, some researchers have suggested alternative interventions to feedback that focus on identifying conditions for success (e.g., Bouskila-Yam and Kluger, 2011; Kluger and Van Dijk, 2010). However, research on alternative interventions to feedback is only in its beginning stages, and the findings are not yet conclusive. Finding effective interventions to improve the feedback process remains one of the challenges for development in this field.

Multisource (360-Degree) Appraisal Technique

Multisource appraisal is one of the most widely used PA techniques in today's organizations (Antonioni, 1996). With this technique, the appraisal of an employee does not rely solely on one source (e.g., manager) but on multiple sources such as managers, peers, subordinates, and clients. Using the multisource technique helps evaluators collect a range of views regarding an employee's performance, with each source adding a unique perspective. For example, a manager can evaluate a nurse on professionalism and compliance to rules, a peer could evaluate how well he or she gets along with colleagues, and a patient could add information on how this nurse treats patients. With multisource feedback, the ratee usually receives the results along with normative data and self-ratings, providing the employee with comparative information (London and Smither, 1995). The purpose of the multisource appraisal is developmental (Brett and Atwater, 2001; DeNisi and Kluger, 2000), namely, to develop and nurture employees and to help them achieve their goals and aspirations, which eventually leads to a promotion focus. As such, use of multisource appraisals assumes to improve employee performance.

Some studies have reported improvements in overall performance following multisource appraisals or upward feedback (e.g., Atwater et al., 1995; Reilly et al., 1996). However, other studies (e.g., Brett and Atwater, 2001; Smither et al., 2005) questioned the effectiveness of this type of appraisal. Specifically, in a meta-analysis, Smither and colleagues (2005) found overall multisource feedback had a small effect on performance improvement. Furthermore, in a longitudinal study on

multisource feedback, Brett and Atwater (2001) found that when ratings were low, employees reacted negatively, expressed anger, and rejected the feedback results. Even when ratings were high, employees did not show positive reactions, as would be expected, but rather, an absence of negative reactions. These findings are especially disappointing because the specific 360-degree feedback that was used in this study was developmental – it was designed to give useful information to the employees without any intention (or capacity) to use the data for other administrative purposes. Thus, despite some positive reported outcomes of the multisource appraisals, "the available data on the effectiveness of these programs is extremely limited, and the conclusions that we can draw from these studies are rather limited" (DeNisi and Kluger, 2000: p. 135).

The most difficult issue in PA is delivering negative feedback to an employee (Ilgen and Davis, 2000). Managers are not enthusiastic to give negative feedback, and employees find it very difficult to accept such feedback (especially if it contradicts their expectations). As a result, workers may become less cooperative and their work performance may suffer, preventing further work improvement and behavioral change. Reactions to negative feedback are influenced by individual differences in self-esteem, regulatory focus, goal orientation, and performance history (e.g., Brett and Atwater, 2001; Ilgen and Davis, 2000); therefore, these factors should be taken into account when negative feedback is given. In addition, the appraisal data should be used only for developmental purposes, and if other uses are considered, this fact should not be hidden from the employees because no PA system can work without mutual trust (DeNisi and Kluger, 2000; Mayer and Davis, 1999).

In view of the challenges and difficulties involved in the feedback process, it is clear that giving feedback demands a high degree of skill and knowledge. However, mastering interpersonal or communication skills is only one part in constituting an effective evaluation system. As mentioned earlier, the social context also is of great importance. This will be addressed next.

The Social Context of the PA Process

The social context in which the PA takes place is crucial to its success. The social context of the PA process consists of issues related to the rater, the ratee, and the relationship between them, as well as to global factors that indirectly affect the PA process such as the organizational culture, legal climate, human resource strategies, and organizational goals (Levy and Williams, 2004). In the following sections, we will review two of the social context factors that are essential to the success of the PA process: procedural justice and leadership.

Perceived Justice of Ratees

Perceived justice appears to be an essential mechanism through which appraisals affect employees' reactions (e.g., Erdogan, 2002; Greenberg, 1986); thus, this has received considerable attention in the PA literature. So how can appraisals be conducted in a fair manner? To answer this question, we need to examine two types of justice described in the literature of justice and fairness that are involved in the PA process: distributive justice and procedural justice. Distributive justice relates to the fairness of the appraisal relative to the exerted effort. Procedural justice relates to the fairness of the procedures that were used to determine the appraisal ratings (Greenberg, 1986). Levels of perceived procedural justice are positively related to important organizational outcomes such as organizational citizenship behavior (Ball et al., 1994; Moorman et al., 1998; Organ et al., 2006; Skarlicki and Latham, 1996, 1997; Whiting et al., 2008), trust in leadership (Barling and Philips, 1993; Folger and Konovsky, 1989; Whiting et al., 2008), organizational commitment, job satisfaction, and performance (Colquitt et al., 2001; Korsgaard et al., 1995).

Folger et al. (1992) have offered a comprehensive model that presents the key variables for designing a procedurally just PA system – the due process model. This model consists of three elements: adequate notice, fair hearing, and judgment based on evidence. Accordingly, the standards for evaluation should be evidence-based, employees should receive early notice about the evaluation standards, and consistent periodical feedback should be given to employees regarding their performance. In addition, employees should be given an opportunity to influence the process during evaluation meetings and to present their opinions (voice).

Several studies have found support for the due process model. Specifically, Taylor and colleagues (Taylor et al., 1998) examined employee–manager pairs that were randomly assigned to two types of evaluations: the customary existing appraisal process versus the due process appraisal. Employees involved in the due process appraisals displayed more positive reactions (e.g., perceived fairness, evaluation of the manager, intention to remain in the organization) than employees in the customary appraisals, even though the evaluations in the due process procedure were actually lower. Further support for the due process model has been found in other studies (e.g., Erdogan et al., 2001; Poon, 2004). Erdogan and colleagues found that characteristics of the due process appraisal (evidence-based criteria and fair hearing) were associated with perceived procedural justice. In addition, Poon (2004) found that when employees perceived the PA process as manipulative and skewed by the political interests of the raters (as opposed to the due process), they demonstrated less satisfaction and higher intention to quit their jobs.

Though the due process guidelines are clear, building a PA system accordingly is a significant challenge, as the performances of different workers are not always comparable and cannot be tested in a similar manner. Unlike student evaluations in which all students receive one standard test at the same time under the same conditions, managers attempting to evaluate their workers face a completely different situation. They do not always have the opportunity to observe all their workers for the same amount of time, and workers are not always performing comparable tasks in terms of difficulty and complexity. Moreover, with today's globalization, managers often supervise their workers from a distance without sufficient opportunity to observe their work, which makes this process even more challenging. Moreover, biases and impression management tactics seem to impact the ratings (e.g., Dulebohn and Ferris, 1999).

Therefore, research in recent years has striven to understand the factors affecting the perceived procedural fairness of PA systems (Erdogan, 2002; Erdogan et al., 2001; Folger et al., 1992) including factors concerning the rater's personality and perceptions (Heslin and VandeWalle, 2011; Mayer et al., 2007), which affect perceived procedural justice. Specifically, managers who exhibit high levels of conscientiousness and agreeableness, in combination with low levels of neuroticism (Mayer et al., 2007), and believe that workers are capable of change (Heslin and VandeWalle, 2011) are perceived as more procedurally just.

Leadership Effect on PA Effectiveness

Another contextual factor influencing the effectiveness of a PA is the manager's leadership behavior (Elicker et al., 2006; Gabris and Ihrke, 2001; Purcell and Hutchinson, 2007; Waldman et al., 1987). More specifically, the exchange relationship between the managers (who perform the evaluation) and their employees (those being evaluated) strongly affects the reactions of the employees to the PA process. The PA session is a 'contact point' (Holbrook, 2002) that is influenced by the existing exchange relationship (Elicker et al., 2006) and by leadership credibility (Gabris and Ihrke, 2001).

The literature on leader–member exchange (LMX) has contributed to our understanding of supervisor–subordinate relationships (Gerstner and Day, 1997; Graen et al., 2006) and their impact on various organizational outcomes (e.g., Fairhurst, 1993; Kacmar et al., 2003; Kark and Van Dijk, 2008). Specifically, the LMX model identifies the supervisor–subordinate relationship as a dyadic social exchange process that is unique to each supervisor–subordinate pair (Graen and Uhl-Bien, 1995). When LMX is high (in-group), the worker receives more attention and support from his or her leader, their relationship is close and warm, and they trust each other. As a result, the worker demonstrates a higher level of performance and has a positive attitude compared with a worker with low LMX (out-group). Given the initial warm and supportive relationship between managers and their in-group workers, it is obvious that during PA sessions, the workers with high LMX will be more confident in their ability to communicate with their managers and, therefore, will achieve more positive outcomes than the out-group workers.

Elicker and colleagues (Elicker et al., 2006) have found that the opportunity for an employee's voice and his or her perception of justice are important mechanisms for the effect of LMX on his or her reaction to a PA. Specifically, they found that the quality of the exchange relationship between leaders and workers affects the opportunity of the workers to voice opinions during a PA session, and as a result, increases the perception of justice, and this perception, in turn, influences workers' attitudes toward the PA process (i.e., motivation, satisfaction, perceived accuracy, and perceived utility). Besides LMX, other leadership behaviors are also found to influence the effectiveness of the PA process. Specifically, transformational leadership has been related to satisfaction with the PA process, whereas transactional leadership has been related to lower satisfaction (Waldman et al., 1987).

Both leadership and procedural justice are important contextual factors influencing the PA success; therefore, attention should be given to these issues while conducting PAs in an organization.

Summary

In this article, we have pointed out some landmarks in the PA literature and discussed the factors threatening the PA process success. Raters' judgment biases and lack of accuracy of the ratings threaten the PA validity. The organizational conditions, which often limit opportunities to observe all workers sufficiently, threaten the procedural justice. Also, the rater does not always master the delicate skills needed for providing effective feedback, and lastly, leadership biases, such as preferring in-group members, are also a possible threat to this process.

PA processes present numerous difficulties and obstacles (e.g., DeNisi et al., 1984; DeNisi and Peters, 1996; Feldman, 1981; Kluger and DeNisi, 1996), and it is safe to say that managers and workers are generally not very satisfied with it (e.g., Bouskila-Yam and Kluger, 2011; Coens and Jenkins, 2002; Peiperl, 2001; Smither et al., 2005). Yet, organizations do not seem to be in a hurry to cancel these evaluations, and existing alternatives are not being adopted. Is this an unfortunate mistake? Possibly, but it is also likely that one of the reasons why the PA process persists is that during it, workers are told who has been successful and who has not, who has reached the top and who is left behind, who has excelled, who is appreciated, and who has achieved something meaningful. By doing this, the PA process relates to the most basic motivational processes that drive people to work in the first place.

Perinatal Psychiatry

Abstract

Perinatal psychiatry covers a wide range of issues that are related to maternal mental health and infant development. The maternal issues include unplanned pregnancy, lack of emotional support by their partners, and domestic violence during pregnancy. Onset of psychiatric disorders is more common in the perinatal period. Postnatal depression is more prevalent than other disorders. More or less 10% of new mothers suffer from depression, and the Edinburgh Postnatal Depression Scale is a well-known screening. The impact of interaction between a mother and a baby on later infant development should be considered, and baby care and family support are important for family well-being.

Introduction

Perinatal mental health is an important issue not only for pregnant and postnatal women but also for their infants and families. Problems widely range from anxiety concerning the delivery, which is commonly experienced, to severe chronic psychiatric disorders, which need formal psychiatric treatment.

Therefore support and treatment for postnatal women is carried out based on women's situations; however, emotional support is essential for all women. Issues to be considered include the mother's emotional bonding to her baby, mother and baby interaction, baby's attachment, and impact of perinatal mental problems on long-term prognosis.

Historically, perinatal mental illness has been recognized since the time of Hippocrates. In the nineteenth century, medical interest in perinatal mental illness increased, in current scope of a general interest in mental illness. Marce, who was devoted to the study of perinatal mental illness, published an important series of case studies of women suffering from various forms of perinatal mental illness over 150 years ago. During the twentieth century, clinical accounts and research on prevalence, risk factors, and consequences to the mother, fetus, and infant expanded dramatically. Recent studies on perinatal mental health have also been influenced by the fetal programming hypothesis. The dynamic mix of biological, socioenvironmental, and psychological factors affects the expression of mental health and illness across the life span. Pregnancy can also be a time of increased stress for women, and the impacts of domestic abuse and relationship strain are related to psychosocial vulnerability not only for women but also for the fetus and developmental prognosis of children. The environment in the womb, during different sensitive periods for specific outcomes, can alter the development of the fetus, permanently affecting the child.

Psychiatric Disorders in the Perinatal Period

Mental illness among women is prevalent in the perinatal period, which starts from pregnancy to postpartum. In a narrow definition, postpartum covers a few weeks after delivery and many studies on postpartum illness consider up to three postnatal months. However, in terms of maternal subjective negative feelings, lack of confidence as a mother, and disturbed mother and infant interactions that last longer even after their symptoms improved, the postnatal period should covered the period of one year after delivery. Some illnesses have new onset in particular during the perinatal period due to drastic psychosocial and relationship changes for women's roles as well as biological changes including rapid hormonal changes. Postnatal depression in particular has a high incidence of more than 10% of all new mothers. Some illnesses may relapse in this period; for example, bipolar illness tends to reoccur during the perinatal period partially because women stop medication in fear of adverse effects on their fetus and obstetric outcome. Also chronic illnesses such as schizophrenia need to be considered as illnesses not only for the possibility of relapse but also for their insufficient maternal skill and less active interaction with their babies. The professionals who care for and treat women with perinatal mental illness should consist of a multidisciplinary team of obstetric, pediatric, and psychiatric medical staff as well as health visitors and social workers in the community.

Anxiety Disorders

A wide range of anxiety disorders are prevalent in the perinatal period, including generalized anxiety, obsessive–compulsive, panic, and social anxiety disorders, as well as depression. Rates of anxiety disorders in the perinatal period vary widely; however, these disorders are less common compared to depression disorders. However, women with anxiety are also depressive at some perinatal point. In a large-scale postpartum screening study with follow-up diagnostic evaluations (Wisner et al., 2013) 66% of women with major depression in the postpartum period had comorbid anxiety disorders. Anxiety and depression are common and they are more prevalent in the perinatal than postnatal period.

Recent findings show that cortisol and pregnancy-specific anxiety independently predicted child anxiety. Children exposed to elevated prenatal maternal cortisol and pregnancy-specific anxiety are at increased risk for developing anxiety problems during the preadolescent period (Davis and Sandman, 2012).

Depression

The incidence and prevalence of prenatal depression has been reported to be from 6% to 38% (Field, 2011); compared to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.27082-7

postnatal depression, prenatal depression was almost twice that of postpartum depression, and the incidence rate was 29% and 17%, respectively (Andersson et al., 2006). Prenatal depression enhances the risk of preterm delivery, which will be related to significant behavioral, cognitive, and emotional problems in children (Li et al., 2009). High prenatal cortisol levels associated with depression may result in elevated fetal cortisol and delayed fetal growth and prematurity (Van den Bergh et al., 2005; Davis et al., 2007; Lundy et al., 1999). Also prenatal depression significantly predicts postpartum depression (Milgrom et al., 2008); therefore these women should be monitored continuously throughout their pregnancies. The risk factors of prenatal depression are past history of depression, lack of emotional and social support from their partner or others, poverty, marital difficulties, increased life stress, substance abuse, a history of previous abortion and ambivalence toward the pregnancy, and anxiety about the fetus. Women with low self-esteem, prenatal anxiety, negative cognitive style, major life events, and a history of abuse are also at risk (Leigh and Milgrom, 2008). Of these items, past history of depression, lack of emotional and social support from a woman's partner or others, and severe life events are also risk factors of postnatal depression. Other relevant risk factors that have smaller associations with postpartum depression include low socioeconomic status, being single, unwanted pregnancy, obstetrical stressors, and difficult infant temperament (O'Hara, M.W. and Wisner, K.L., 2014).

The mood of women after delivery is labile and most of them can be weepy, especially in the first 10 days after delivery. Women tend to cry for unexplained sadness or feel a little bit high. This phenomenon is called postpartum blues. It is very common, and more than half of postnatal women experience crying dysphoric mood or sometimes an elevated high feeling, insomnia, anxiety, irritability, loss of appetite, and headaches. These phenomena usually disappear within a couple of days and nonspecific treatment is necessary.

Postnatal depression is common among women, and while they are celebrated for a baby's birth, their depressed feelings are not disclosed easily. Incidence is higher than the one in the non-postnatal period, and diagnosis of depression and antidepressant prescriptions are increased to more than 14% (Davé, S. et al., 2010). Apart from the risk factors mentioned earlier, the relevant risk factors that have smaller associations with postpartum depression include low socioeconomic status, being single, unwanted pregnancy, obstetrical stressors, and difficult infant temperament (O'Hara, M.W. and Wisner, K.L., 2014).

Screening for Postnatal Depression

Most mothers with postnatal depression are unlikely to access psychiatric care, even though their symptoms are serious (McIntosh, 1993). Therefore, neonatal home visits by health visitors are regarded as a potentially useful opportunity for detecting mothers with postnatal depression. A home visit system by community health visitors has been organized in many countries. In the past, the purpose of the visit was to promote infant growth and development. Health visitors tend to focus on the baby's physical health rather than on any potential psychological problems that the mothers may have. Underestimating mothers' mental health seemed to be common and mental problems were easily overlooked even by those professionals unless a mother asked for their help.

The Edinburgh Postnatal Depression Scale is most commonly used for screening by midwives and health visitors. Women are often asked to complete this 10-item questionnaire that asks about depression and anxiety-related symptoms over the recent 7 days. Scores can range from 0 to 30, and women whose scores exceed a specified threshold (usually between 10 and 13 in European and American countries, but it depends on their culture and countries) are often referred for further evaluation or treatment for a perinatal depressive or anxiety disorder (Cox, J. et al., 1987).

Puerperal Psychosis

Postpartum psychosis occurs rapidly after birth, usually within a few days after delivery. The symptoms are mood fluctuation, confusion, delirium, bizarre behavior, insomnia, and visual and auditory hallucinations.

Recent studies showed that bipolar disorder is very important to be recognized and treated properly, because half of the suffering women are undiagnosed (Sharma, V. et al., 2009). Mothers could kill their babies due to their delusions or distorted beliefs. Women are vulnerable to affective psychoses after birth more than at any other time during their lives (Munk-Olsen, T. et al., 2009).

Childbirth was associated with an increased risk of readmission during the first postpartum month, and a previous diagnosis of bipolar affective disorder was the strongest predictor of readmission. Postnatal women with current chronic psychosis need to be monitored early in the postnatal period, especially in the first month after delivery. With regard to bipolar disorders, Munk-Olsen et al. (2009) reported a population-based study of 28 124 women, of which they reported that the prevalence of incident admissions among new mothers was 0.1% at up to 4 months postpartum and readmission due to recurrence of a mental disorder occurred even more often.

Suicide and Infanticide

The United Kingdom Confidential Enquiry into All Maternal Deaths between 1997 and 1999 revealed that 10% of postpartum deaths resulted from suicide, and 12% of maternal deaths resulted from psychiatric causes such as accidental overdose, deaths from medical conditions due to substance use, and violent deaths (Oates, 2003). Furthermore, maternal suicide can be associated with a risk of infanticide (Brockington, 2001). It is a rare event; therefore intervention and treatment should be carried out.

Mother and Infant Interaction and Related Problems

Maternal Bonding Disorder toward Her Baby

Maternal emotional involvement with the baby in the perinatal period has been recognized and named 'bonding' and has been mainly discussed in relation to postnatal depression. Although some depressed mothers maintain positive maternal attitudes toward their newborn babies, a proportion of depressed

mothers experience severe negative affection toward their infants (Kumar 1997). Preliminary work by Kumar (1997), using items selected from mothers' narrative accounts, resulted in the development of a self-report screening scale, the Mother–Infant Bonding Questionnaire (MIBQ). This scale has nine items: loving, resentful, neutral or felt nothing, possessive, joyful, dislike, protective, disappointed, and aggressive. The MIBQ was later modified by Kumar's colleague Marks. Compared with the original questionnaire, the wording was changed in three items and the item 'scared or panicky' was newly added, resulting in a total of 10 items (Yoshida et al., 2012).

Based on interview responses, Brockington et al. (2006a) interviewed severe disorders of the mother–infant relationship in over 200 mothers. They found that depressed mothers had normal or disturbed mother–infant relationships and nearly one-third of the mothers had pathological anger toward the baby, and more or less the same rate of mothers had rejection or threatened rejection of the baby. They developed a questionnaire regarding bonding disorder and reported its validation (Brockington et al., 2006b).

Maltreatment and Poor Mothering by Mentally Ill Mothers

The multiple psychosocial difficulties experienced by women with mental disorders can have adverse effects on the development of mother–infant attachment and the child.

Kumar et al. (1995) investigated 100 consecutive admissions to a mother-and-baby unit. They reported that the proportion separated from their infant on discharge was 50% among the group with schizophrenia, and the proportion was much higher compared to the group with affective psychosis or nonpsychotic disorders (8% and 4%, respectively). The babies born to the mothers with schizophrenia had lower birth weights compared to the babies born to mothers with affective disorders, and with poor parenting, the developmental outcomes of those infants are worse compared to those of the other groups of mothers (Yoshida et al., 1999).

Adverse Impact of Maternal Psychosocial Vulnerability and Mental Illness on Child Development and Outcome

Maternal mental illnesses and various psychosocial difficulties during the perinatal period affect both the physical and mental development of a newborn. Prenatal depression has been associated with excessive activity and growth delays in the fetus as well as prematurity, low birth weight, disorganized sleep, and less responsiveness to stimulation in the neonate (Field, 2011). Over the past 15 years, several studies have examined associations between postnatal depression and child outcome longitudinally (Sutter-Dallay, A.L. et al., 2011) Depressed mothers lacked responsiveness to infant cue, that leads to difficulties in mother–infant relationship in the first year, as well as insecurity in the mother–infant relationship at 18 months (Murray, L., 2009). The association between postnatal depression and children's cognitive outcome may be related to the severity, persistence, or recurrence of maternal depressive symptoms beyond the postpartum period (Sutter-Dallay, A.L. et al., 2011). Long-term support and intervention for both mothers and infants can be ideal and effective.

Treatment and Service Plan

Perinatal mental illness refers to psychiatric disorders that are prevalent during pregnancy and as long as one year after delivery. Therefore, a multidisciplinary approach is necessary. The obstetric staff should be involved first in evaluation, detection, and preventive care for women at risk or with mental illness. Obstetricians and midwives should be aware of risk factors for perinatal mental illness, care and treatment, and referral options. However, most women at risk or who already have mental disorders would not actively ask for support. Therefore screening and early intervention are necessary. Quite often the different specialists have to collaborate with each other from the time of pregnancy and hand over their evaluations and care reports to other staff.

Psychosocial Interventions

Obstetricians and hospital or community midwives can identify women with past or present mental illness including schizophrenia, other psychoses, depression, substance abuse, a family history of perinatal psychiatric disorder, as well as psychosocially vulnerable women suffering domestic violence. Women identified at risk need to be referred to specialist perinatal mental health professionals for further assessment, specific interventions, and the monitoring of their mental health both during pregnancy and postpartum.

Psychological therapies are usually recommended as the first line of treatment for mild-to-moderate postnatal depression for women with no previous history of mental health conditions. Home visits by community-based health visitors can be carried out as a psychosocial intervention of psychiatric illness. Psychoeducation and emotional support for the partner and other family members is important, and family members should be kept informed of the patient's condition, treatment plan, and expected outcome. Help with nocturnal infant care should be recommended to minimize the mother's sleep disruption. Once the mother's condition is stable, issues such as parenting skills and maternal–infant bonding should be addressed. Cognitive behavioral therapy (CBT) and interpersonal therapy (IPT) (Dennis, C.-L. and Dowswell, T., 2013; Milgrom, J. et al., 2005; Kopelman, R. and Stuart, S., 2005) are effective for depression and maybe for other psychological and psychiatric disorders. CBT is a type of therapy based on the idea that unhelpful and unrealistic thinking leads to negative behavior. CBT aims to break this cycle and find new ways of thinking that can help a woman behave in a more positive way. IPT aims to identify whether her relationships with others may be contributing toward feelings of depression.

Pharmacological Management

Selective serotonin reuptake inhibitors (SSRIs) are advised for treatment for pre- and postnatal depression. Rapid and abrupt hormonal changes over the course of delivery also contribute to onset of depression.

Estradiol levels rapidly decrease due to placenta delivery. Monoamine oxidase A levels increase and neurotransmitters such as serotonin, dopamine, and norepinephrine are depleted, which are the triggers of the onset of depression (Sacher et al.,

2010). Three neurotransmitters have been implicated in prenatal depression, including elevated norepinephrine and low levels of dopamine and serotonin, which were noted in depressed pregnant women (Lundy et al., 1999). SSRIs are used for pharmacological treatment. Very few adverse effects of SSRIs are reported such as neonatal withdrawal syndrome (Sanz et al., 2005) and infant pulmonary hypertension (Chambers et al., 2006). Discontinuation of antidepressants or antipsychotic drugs can often lead to relapse. If women are very reluctant to take medication in pregnancy, it is recommended to take medication immediately after delivery.

In case of bipolar depression, treatment with antidepressants resulted in a highly unstable illness course, and discontinuation of antidepressants and initiation of mood stabilizers and atypical antipsychotics resulted in sustained improvement (Sharma et al., 2009). The significant impacts of prophylactic treatment with mood stabilizers and antipsychotics on postpartum mood episodes in women with bipolar I or II disorder have been reported in clinical studies. Treatment during lactation requires minimizing infant exposure and adverse effects while maintaining optimum maternal mental health. In women with depressive disorder or bipolar disorder, the benefits of breast-feeding should also be carefully balanced against the deleterious effect of sleep deprivation in triggering mood episodes.

The effectiveness of the use of lithium, carbamazepine, divalproex, and olanzapine was reported in the reduction of postpartum recurrences. Carbamazepine and valproic acid are reported to be teratogenic and should be avoided in only early pregnancy. Women on lithium should have a slow reduction of lithium to reduce the risk of relapse. In these women, the risk of untreated psychiatric illness outweighs any risk to the fetus from exposure to psychotropic medications (Oyebode et al., 2012). The most important strategy is to evaluate maternal mental problems and symptoms and try to reduce their problems.

Treatment might also include complementary and alternative treatments, such as exercise, bright light therapy, and yoga. Massage therapy and psychotherapy reduce cortisol levels and they have been tried for women with postnatal depression. Treatment is usually on an outpatient basis, although psychiatric emergencies, such as suicidal thoughts with a plan and intent, or postpartum psychosis, warrant hospitalization.

Conclusion

Maternal prenatal and postnatal psychiatric disorders are related to their psychosocial and biological vulnerability, which disturb mother and infant interaction and baby care function, and those are a negative impact on infants' later development and their well-being in adolescence. This long-term influence should be noted when caring for and treating women with perinatal psychiatric disorders because those adolescents will be the parents at risk in the next generation. Psychiatry is a cultural issue as well as medical one (Bhugra and Bahl, 1999). Strategies to deal with perinatal psychiatry in particular need to be focused on patients' cultural backgrounds. A life cycle and cultural perspective is important to addressing the challenges of this complex period.

Abstract

This article reviews the long-standing analytic problem in period and cohort analysis in demography about the conceptualization, estimation, and interpretation of the differential contributions of distinct time-related changes attributed to period- and cohort-based sources of change in demographic phenomena. It introduces innovative approaches that emerged in recent methodological and substantive research on this problem using three common research designs and the generalized linear mixed effects modeling framework. It also outlines some promising areas of study that employ and extend these approaches in various important topics in contemporary demography.

Introduction

Demography is fundamentally concerned with time-varying phenomena. Key components of population changes such as fertility, mortality, and migration are always measured as age- and time-specific events. While age is by far the most important source of temporal variation in vital rates, historical time and birth cohort are the other two dimensions of time that have preoccupied much attention in statistical studies of human populations. Indeed, the vast majority of quantitative demographic research accounts for period-based or cohort-based temporal processes, with researchers making implicit assumptions about each temporal dimension's role in driving population change. Such assumptions usually translate to fitting analytic models that favor one dimension over the other, with the other excluded outright. A question that cannot be escaped, however, is the tenability of such assumption, which can only be tested in analyses that simultaneously include measures of both period-based and cohort-based changes. In this article, we review the long-standing analytic problem in demography about the conceptualization, estimation, and interpretation of the differential contributions of distinct time-related changes in demographic phenomena, especially period- and cohort-based sources of change. We introduce innovative approaches that emerged in recent methodological and substantive research on this problem. We refer interested readers to a recent book that introduces new guidelines for cohort analysis by Yang and Land (2013) for greater details. Finally, we outline some promising areas of study that employ and extend these approaches, and breathe new life into period and cohort analysis in demography.

Conceptualizations

A fundamental characteristic of demographic research is the study of age-specific data recorded at different points in time and from different birth cohorts. As illustrated in **Table 1**, a typical data set takes the form of an age (a30, a40, a50, a60) by period (p1970, p1980, p1990, p2000) array of outcomes where birth cohorts fall on the diagonals (c1910, c1920, … c1970). What often demands demographers' attention is the depiction of variation in such data along one or more of these temporal dimensions: (1) the ages of the individuals at the time of observation, termed 'age' (A) effects, (2) the time periods of observation or measurement of the outcome, termed 'period' (P) effects, and (3) the year of birth or another shared life event for a set of individuals, termed 'cohort' (C) effects.

Since the discovery of the Gompertz law, studies of the A effects have long existed in the history of population science. Studies that jointly consider P and C variations as distinct entities from A effects, termed as the 'age-period-cohort' (APC) analysis, appeared relatively recently (see, e.g., Hobcraft et al., 1982, for a review). Of central focus in the APC analysis is the distinction of P and C effects as the other two components of temporal variation in demographic outcomes. The meanings of P and C effects can be most differentiated by contrasting them in specific demographic contexts. Here we focus on their conceptualizations in the context of health, chronic disease, and mortality.

Period (P) effects are variations over time periods or calendar years that simultaneously influence all individuals. They subsume a complex set of historical events and environmental factors such as world wars, famine, and pandemics of infectious diseases, rapid adoption of technological advances, or economic expansions and contractions. Period effects are often evident from a correspondence in the timing of changes in outcomes and conditions that induced these outcomes. They can also arise from changes in disease classification or diagnostic techniques. For example, increases in breast cancer death rates from 1970 to 2000 were found to result from increases in mammography usage, and hence detections of malignant cases during this period, whereas the subsequent downturn in death rates starting around year 2000 was due to the sudden reductions of hormone replacement therapy usage (Yang and Land, 2013: Figures 8.7

Table 1 Hypothetical data arrayed by age, period, and cohort

	p1970	*p1980*	*P1990*	*p2000*
a30	c1940	c1950	c1960	c1970
a40	c1930	c1940	c1950	c1960
a50	c1920	c1930	c1940	c1950
a60	c1910	c1920	c1930	c1940

and 8.9). Similar period-based changes in mortality from heart disease have been observed in the U.S. population following the introduction and widespread use of pharmacological technologies to manage cholesterol (e.g., statins), hypertension (e.g., beta blockers and other antihypertensive drugs), and myocardial infarction (e.g., stents) (Lloyd-Jones et al., 2009).

Cohort (C) effects are also observed in many processes related to population health and mortality. A birth cohort ages together, encountering the same historical and social events at the same stage of the life course. The exit of an old cohort through death is constantly being replenished by the entry of a new cohort through birth, thereby continuously shaping and reshaping a population's composition. This continual process of cohort succession and replacement has long been recognized as an essential component of 'demographic metabolism' driving social change (Ryder, 1965). Further, variation across cohorts can arise from differential exposure to early life conditions and life-long accumulation of exposures to physiological, socioeconomic, behavioral, and environmental risk factors from gestation to old age (Fogel and Costa, 1997; Ben-Shlomo and Kuh, 2002; Finch and Crimmins, 2004). Importantly, cohort membership operates as a contextual characteristic for the understanding of the heterogeneous experiences of aging. Indeed, the 'principle of cohort differences in aging' posits that each cohort ages across the life course in unique and identifiable ways (Riley, 1987).

Challenges to Estimation and Interpretation

The conceptualizations of period and cohort effects suggest that these two are distinct sources of demographic variation driven by different population processes. However, such distinctions are often difficult to discern in empirical studies. As a result, period and cohort effects are frequently confounded with each other and also confounded with the age effects. We now briefly explain challenges to the estimation and interpretation of period and cohort effects in applications of conventional methods of APC analysis.

Descriptive Analysis

The vast majority of demographic studies that are concerned with time trends rely on descriptive techniques that provide qualitative impressions about temporal patterns. One common practice uses summary measures that are independent of age composition, such as standardized indices (e.g., age-standardized death rates) arrayed by time periods. An alternative device is a graphical display of the two-way table of age-period-specific rates or age-cohort-specific rates. Using **Table 1** as an example, one can plot the age-specific data for a30 to a60 for each of the time period, p1970 to p2000, and compare how the age patterns differ across the periods. Plotting the age-specific data for each of the birth cohort, c1910 to c1970, would similarly enable the comparison of cohort differences in the age patterns.

Although comparisons of trends based on these descriptive measures almost always have implications for the P and C effects underlying the observed data, neither approach explicitly adopts a formal modeling framework for the attribution of differential contributions of each to the phenomena under study (Hobcraft et al., 1982). These types of descriptive analyses share two disadvantages. First, they only describe variation in the demographic outcome associated with period or birth cohort, thereby making implicit assumptions about the lack of influence of the omitted dimension. Thus, the possibility of confounding of the two factors cannot be tested. Second, neither approach summarizes the corresponding data table satisfactorily. Standardization ignores different trends at different ages and graphical methods represent all available data, providing no summary at all (Osmond, 1985). Moreover, each approach has its own limitations. Standardized rates by definition depend on the age composition of a particular period that is used as the standard, and give more weight to rates at older ages. The substantive conclusion about time changes in these rates can thus be sensitive to the choice of the standard, which might have changed drastically over the past few decades due to the substantial population aging of many populations. The use of a more recent year as the standard would yield higher rates than using a younger population in a much earlier year.

The graphical presentation of all data can also produce inconsistent conclusions. For example, **Figure 1** shows the age-specific rates of lung cancer incidence for white females for years 1969–2007. The age curve in any given time period, say 2000–2004, cuts across a number of birth cohorts, including 1920, 1925, and 1930. Therefore, the shape of the period curve is affected by both varying age effects and cohort effects. It is not possible to determine how these effects operate simultaneously to shift period curves. To obtain a quantitative assessment of the source of change in the data, one needs to use statistical regression modeling (Kupper et al., 1985).

Linear Regression Models for APC Analysis

Linear regression models have been long used in quantitative social science research to account for the variation in demographic phenomena. The standard models for the APC analysis of age-by-time period data in the form of **Table 1** were known as the APC accounting/multiple classification models, which were introduced by Mason et al. (1973) as a general methodology for analysis when age, period, and cohort variables are all potentially of interest. The general form of the model can be written in linear regression form as:

$$f(y_{ijk}) = \mu + \alpha_i + \beta_j + \gamma_k \qquad [1]$$

where y_{ijk} denotes the observed outcome for the ith age group for $i = 1, \ldots, a$ age groups at the jth time period for $j = 1, \ldots, p$ time periods and of the kth cohort for $k = 1, \ldots, (a + p - 1)$ cohorts, with $k = a - i + j$; $f(.)$ is a simple transformation (linear, log, or logit); μ denotes the intercept or adjusted mean; α_i denotes the ith row age effect or the coefficient for the ith age group; β_j denotes the jth column period effect or the coefficient for the jth time period; γ_k denotes the kth diagonal cohort effect or the coefficient for the kth cohort.

Methodological Problems

In spite of its theoretical merits and conceptual relevance, conventional APC analysis suffers from a major methodological problem, which is inevitably a function of applying the

Figure 1 Age-specific lung cancer incidence rates for white females by time period and birth cohort.

linear regression model specified in eqn [1]. The "identification problem" occurs when both of the following conditions are satisfied (Mason et al., 1973): (1) A, P, and C are linearly related to each other, that is, A + C = P; and (2) each variable is postulated to be linearly related the outcome y_{ijk}. In the application of the linear models to data organized in the particular structure as shown in **Table 1**, this problem can be viewed as a special case of collinear regressors that produces a singular matrix (of one less than full rank) used in the statistical estimation process. Since a singular matrix produces multiple estimators of the three effects, it is statistically impossible to separately estimate the unique, true effects of each temporal dimension. Greater algebraic detail of this problem is available elsewhere (Yang and Land, 2013). The linear models dominated APC analysis for so long that analysts seldom reflect upon their deficiencies. There is confusion about the origin of the problem that it is inherent in the data because the A, P, and C variables are almost always exactly linear when measured in the same interval length, as is the case for major demographic data on vital rates. As a result, previous studies were almost exclusively focused on finding solutions to break condition (1) while paying little attention to condition (2). This will become clear in our discussion of conventional solutions below. A new insight into the old problem, therefore, is that the problem is model specific rather than data specific.

Conventional Approaches and Limitations

One commonly adopted approach is to estimate a reduced age and period or age and cohort two-factor model. This strategy does not incur the identification problem and simplifies the estimation considerably. The greatest challenge to the validity of this approach is the potential spuriousness of the estimated period or cohort effects due to the other effect being omitted from the model. For example, early studies of mortality infrequently tested cohort effects. More recent studies have found results strongly suggesting its presence, implying that certain assumptions previously used by demographers to analyze mortality trends may have been incorrect. Indeed, the recent evidence suggests that rates of U.S. mortality declines were likely associated with period-specific conditions – such as economic advance and health care technology – as well as being differentially experienced by birth cohorts. The latter finding implicates cohort-related changes in early-life conditions, cohort differences in intergenerational transfers of health capital, and/or cohorts' disparate exposures to health-enhancing technologies in recent historical declines in U.S. mortality levels (Finch and Crimmins, 2004; Fogel and Costa, 1997; Masters, 2012; Masters et al., 2012, in press; Yang, 2008a). Consequently, the omission of cohort effects from mortality models concerned with trends would likely be misspecified and inconsistent with accumulating evidence for cohort changes in population health.

Another widely adopted approach to estimating eqn [1] is the constrained generalized linear models (CGLIMs) approach. Here, one or more additional identifying constraint (usually an equality constraint) can be placed on the parameter vector to just identify or overidentify the model. Using the data in **Table 1** as an example, letting the effects of a30 and a40 be equal would just identify the model and yield unique estimates for A, P, and C effects. Grouping multiple ages, periods, or cohorts into less-refined categories would be one kind of overidentifying constraint that would also yield unique estimates of these effects. Discussions of problems with this CGLIM approach can be found elsewhere (Mason et al., 1973; Yang et al., 2004). The major limitations included that the choice of constraints relies on external information that usually cannot be found or validated and hence can only be arbitrary, that different choices can also produce different estimates of P and C effects, and that all just-identified models will produce identical model fit statistics. The latter makes it impossible to discriminate among different constrained models.

There are other approaches that focus on the linear dependency problem in the data such as nonlinear parametric

transformation of one or more of the A, P, and C variables (Mason and Feinberg, 1985), the proxy variables approach that substitute one of these variables with measured characteristics (O'Brien et al., 1999; Winship and Harding, 2008), and those used frequently in biostatistics such as estimable functions of nonlinear components of trends and the minimization of penalty function for the derivation of linear constraint (Robertson et al., 1999; Holford, 2005). A detailed review of these methods is included in Yang and Land (2013). The most important limitation shared by all the conventional approaches discussed above is that they are confined to the linear models framework that necessarily incurs the identification problem.

Theoretical Problems

The lack of a proper understanding of the origin of the model identification problem also contributed to conceptual limitations. While the problem has always been conceived as a methodological one, we believe it is also a theoretical one. The APC accounting models induce this problem by imposing the key assumption of additivity and treating the three variables as fixed effects that are independent of each other. That is, the outcome is modeled as a function of $A + P + C$. This is a simple approximation to the actual processes underlying social change and may not accurately describe period- and cohort-related phenomena. A new framework is needed to accommodate nonadditive and random processes in addition to additive and fixed effects; to better characterize the cohort and period effects; to stimulate new conceptualizations of processes of change at multiple levels (individual, historical time, and their intersection); and to address new theoretical questions about change.

New Approaches to Old Problems

In recent decades, new statistical models and computationally intensive estimation methods have been developed. Also, data sets with research designs that invite or even require accurate period and cohort analysis have become more available. Together, new possibilities have emerged for sophisticated analyses of period- and cohort-based demographic processes. In a recent book, Yang and Land (2013) presented guidelines for conducting APC analysis that provide new avenues to approaching the old problems outlined above. Using three research designs, they showed the application of a generalized linear mixed models framework to the analyses of time related dynamics and population heterogeneity therein.

Three Useful Research Designs

While the use of cross-section design leads to the confounding of age and cohort effects, and the use of single-cohort panel design leads to the confounding of age and period effects, three other research designs are particularly useful for period and cohort analysis.

The repeated cross-sectional data design subsumes two subcategories that are similar in form but different in unit of analysis. The first is the age-by-time period tabular array of population-level rates or proportions, the classical data structure fit to the linear models in eqn [1]. As depicted in **Table 1** and **Figure 1**, age-specific observations of aggregate rates can be summarized in an A by P table for age groups and time periods that are of equal interval lengths. The diagonal elements of the matrix correspond to observations of birth cohorts. Only a longitudinal panel study design provides data on true birth cohorts, which follow identical individuals over time. That said, repeated cross-sectional designs are far more common and rely on the synthetic-cohort approach that repeatedly samples the same birth cohort over a long period of time. Differential temporal groupings for the A, P, and C variables are also possible using this design. When the data used to construct the A by P array are in such a form that different interval widths are used for the variables, the same design can be considered alternatively as a multilevel data design. Some prototypical data sets that used this design include death rates in the Human Mortality Database, and cancer incidence and mortality rates in Surveillance, Epidemiology, and End Results.

The second design is a repeated cross-sectional sample survey that also contains microdata on individual respondents. Pooling data by birth cohorts and survey years, one can obtain the cohort-by-period cross-classification data structure, in which multiple individual observations are nested within the cross-classifications of two higher level units – birth cohort and time period. Although this design shares characteristics with tabular data at the aggregate population level, it also possesses an additional and important feature: it provides multilevel data on both the individual-level responses and a wide range of covariates. These features enable much finer-grained analyses in these data than those structured entirely from aggregated cross sections. Some prototypical data sets that used this design include the General Social Survey, the National Health and Interview Survey, and the National Health and Nutritional Examination Survey.

The third design is the prospective cohort panel and the accelerated longitudinal design that follows multiple cohorts forward over multiple points in time. Such a structure provides cross-time linkages within individuals in true cohorts. This design has been an important advance in aging and life course research because it allows a more rapid accumulation of aging information from multiple cohorts. It is thus especially useful for testing aging- and cohort-related hypotheses because it allows the distinction between intraindividual change with age within cohorts and intercohort differences in age trajectories. Some prototypical data sets using this design include the Americans' Changing Lives Study and Health and Retirement Study.

The Intrinsic Estimator for Linear Regression Models

A number of recent methodological studies have introduced an innovative approach to the model identification and estimation problem concerning period and cohort analysis within the linear/generalized linear models framework. Incorporating recent methodological developments on estimable functions in the context of the APC accounting model, the Intrinsic Estimator (IE) was proposed as a new method of estimation for distinct age, period, and cohort effects. The uniqueness of the IE

is its property of estimating the unique estimable function of all components of the model (1) determined by the Moore–Penrose generalized inverse. It achieves model identification with minimal assumptions about the individual effects included in the model. Further, it can be estimated using principal component regression. The IE is another constrained estimator, but the special constraint used by the IE is to remove the influence of the design matrix (which is fixed by the number of age and period groups and not related to the outcome y_{ijk}) on coefficient estimates, thus allowing the intrinsic trends of variation in the data to emerge. This constraint produces an estimator that has desirable statistical properties, including estimability, unbiasedness, relative efficiency, and asymptotic consistency (Yang et al., 2004). The IE method can be implemented in multiple statistical packages such as R and Stata. Interested readers should refer to the book website for Yang and Land (2013) for sample codes.

To date, the IE has been empirically applied in a number of studies in epidemiology, demography, and social science, and has yielded sensible results on period and cohort trends in a variety of topics, such as cause-specific mortality rates (Yang, 2008a; Masters et al., in press; Powers, 2013), rates of religious activities and beliefs (Schwadel, 2011), and mortality due to accidental poisoning (Miech et al., 2011). Additional methodological studies of its properties have also continued. For example, Powers (2013) couched the IE in a longer statistical tradition of estimable functions, showing "a number of equivalent numerical methods (i.e., principal components, singular value decomposition, generalized inverse, etc.) may be employed in various ways to provide solutions." And Powers's (2012) work provides a flexible extension (ie_rate) of Schulhofer-Wohl and Yang's (2006) APC IE Stata program (apc_ie). In addition, Yang and Land (2013) have further illustrated the robustness of the statistical properties of the IE via Monte Carlo simulation and empirical model validation analyses. They demonstrated numerically the finite-time-period and asymptotic properties of the IE. They also showed that the IE results are completely consistent with coefficient estimates of age, period, and cohort effects from an entirely different family of models (hierarchical APC models, which are discussed below) that do not use any identifying constraints. Similarly, Masters et al. in press found estimates of temporal trends in official U.S. adult mortality rates from models using the IE to be entirely consistent with coefficient estimates from Hierarchical Bayesian Models using Gibbs sampling (Yang, 2006).

Hierarchical Age-Period-Cohort Models

We noted before that there are theoretical limitations of the conventional linear models for analysis of period and cohort effects. And these limitations call for a better modeling framework that can generalize various processes underlying these effects. The mixed effects models are one family of models that satisfy this criterion, which we term as the 'hierarchical APC' or 'Hierarchical Age-Period-Cohort' (HAPC) models. We emphasize two breakthroughs of HAPC models compared to the linear fixed effects models. First, because individual-level observations are nested in higher-level social contexts defined by time period as well as birth cohort, we can contextualize individual lives within periods and cohorts by employing hierarchical linear models that both address multilevel heterogeneity and avoid the model identification problem. Second, the HAPC models allow for the testing of mechanism-based explanatory hypotheses through the inclusion of additional covariates at both the individual and period- or cohort-levels. Hence, this new family of models can also effectively address the criticism lodged against the general purpose APC analysis: namely, that it is not useful because it does not reveal any underlying mechanisms driving the observed period-based and cohort-based trends.

Recalling the two conditions inducing the identification problem, (1) the use of multilevel data resolves the first condition such that no exact linear dependency exists between A, P, and C variables, and (2) the new HAPC models can be specified so that the three variables are not linearly related to the outcome. The combination of both approaches is the most effective way of accounting for change. In the APC accounting model, the assumption of fixed period and cohort effects ignores the level-two heterogeneity. In the HAPC models, one can model the level-two heterogeneity directly to assess the possibility that individuals within the same periods and cohorts might share unobserved random variance. Specifically, one specifies the cross-classified random effects model (CCREM) as the following:

Level-1 Within-cell model:

$$f(y_{ijk}) = \beta_{0jk} + \sum_{p=1}^{P} X_p \beta_p \qquad [2]$$

Level-2 Between-cell model:

$$\beta_{0jk} = \gamma_0 + u_{0j} + v_{0k} \qquad [3]$$

In the level-1 within-cell model, β_{0jk} is the intercept or 'cell mean,' that is, the mean outcome value of individuals who belong to birth cohort j and surveyed in year k; the outcome variable of respondent i within each birth cohort j and survey year k is assumed as a function of a vector of individual-level covariates, X_p, for $p = 1, \ldots, P$, where P indicates the maximum number of covariates and $\beta_1, \ldots, \beta_p$ are the level-1 fixed effects. In the level-2 between-cell model, the intercept β_{0jk} is allowed to vary randomly from cohort to cohort and from period to period. γ_0 is the model intercept, or grand-mean; u_{0j} is the cohort effect, or residual random effect of cohort j, that is, the contribution of cohort j averaged over all periods, on β_{0jk}, and v_{0k} is the period effect, or residual random effect of period k, that is, the contribution of period k averaged over all cohorts.

A two-step approach can be used to assess the statistical significance of random period and cohort effects. In step , one studies the patterns and statistical significance of the individual estimated coefficients for birth cohorts (u_{0j}) and time periods (v_{0k}). The random coefficients and their standard errors can be obtained by the restricted maximum likelihood-empirical Bayes estimation (REML-EB) available in most statistical packages such as SAS and Stata that also

reports their ratios as asymptotic *t*-ratios for the statistical test. In step 2, one further assesses whether the birth cohort and/or time period effects, taken as a whole, are also statistically significant. This question is one of whether these effects together contribute to explained variance in the model. A first approach to this question is to examine the model deviance statistics, variance components, and associated *z*-scores using the REML-EB method. When the numbers of level-two units (cohorts and periods) are small, however, the large sample properties of random effect estimators may not be appropriate and the REML estimates of the variance components are only proximate. In this case, one can use an *F* test to test the hypothesis of the presence of random effects. The specific procedures are available in Yang and Land (2013: Chapter 7).

The basic model shown above in eqns [2] and [3] is a *random-intercept model* that allows only the level-1 intercept to have random variations. It can be extended to become a *random-coefficient model* wherein level-1 slope coefficients also have random variations across cohorts and periods. The random-intercept model is useful for assessing the period and cohort trends in mean outcomes. And the random-coefficient model is more general and can be useful for assessing period and cohort trends in not only the mean but also slopes of level-1 fixed effects that may define social inequalities (e.g., sex, race, education) in the outcomes. For example, a recent study of social disparities in happiness in the United States used the random-coefficient CCREM to show that racial gaps in happiness changed significantly over time, but were constant across birth cohorts (Yang, 2008b). One can further add level-two covariates to explain the cohort or/and period variances. An example is that cohort patterns of newspaper reading and TV watching were found to explain part of the recent cohort-based declines in U.S. verbal ability (Yang, 2006). In all, the HAPC models provide a much more flexible framework than the linear models, move far beyond the identification problem, and can accommodate a wide variety of specifications to address complex questions related to demographic phenomena.

New Areas of Period and Cohort Analysis

Period and cohort analysis, together with the model identification problem, have intrigued and frustrated demographers for decades. Developments of new estimation methods – and the extensions of more general models summarized above – have brought renewed interest to such analysis (Smith, 2008). With increasing applications of new models and methods, the scope of period and cohort analysis is quickly expanding. It is beyond the scope of this article to offer an exhaustive review of all newly emerged directions of research. We briefly provide some examples that highlight new areas of methodological and substantive research relevant to demography.

APC Model-Based Demographic Forecasting

When period and cohort factors are both implicated in demographic patterns and trends, the forecasting of future rates of change needs to account for both effects. Indeed, omitting either period-based or cohort-based variation from trend models will likely lead to inaccurate forecasts. By design, an APC framework for analyzing trends in demographic outcomes can be easily extended to forecasting future population trends. For example, a simple application of the APC model-based forecasting analysis shows that it was able to predict the slowdown of coronary heart disease mortality decline among men ages 45–49 and increases among men ages 25–29 after 2000. Such trends can likely be attributed to changing health conditions in more recent cohorts, such as rising obesity prevalence and increasing duration of time spent obese across early life (Reither et al., 2011). Previous work relying on traditional forecasting methods was inattentive to these changes, and inaccurately forecasted coronary U.S. heart disease mortality among these age groups.

Yang and Land (2013) further compared the performance of traditional forecasting methods with the APC model-based projections in predicting future cancer mortality rates. The conventional models tested were (1) simple linear extrapolation and (2) time series methods such as the autoregressive integrated moving average (ARIMA). The difference between these two kinds of forecasting is that the simple method produced future rates by (1) fitting linear or (2) ARIMA models to mortality rates, whereas the APC method forecasted future rates by fitting the same models to APC model coefficients. The results of internal validation analysis showed unequivocally that the APC approach was able to depict actual mortality rates much better by their accounting for cohort changes in trends. Such cohort-based changes were missed by both traditional methods, leading to less accurate predictions.

Thus, the APC model based demographic forecasting methods have shown substantial advantages over the simple data extrapolation methods in accuracy of point forecasts and assessments of uncertainty in these forecasts through prediction intervals. Therefore, they hold much promise for demographic studies of cohort processes and their implications for future trends of population change.

Temporal Dynamics in Population Heterogeneity

Period and cohort analysis have traditionally been utilized to document temporal trends and dynamics in population-wide processes. Recent studies have paid increasing attention to systematic temporal variations in health behaviors and health inequalities across subgroups. We briefly mention three categories of research that focuses on heterogeneity in terms of either variations by specific sociodemographic groups or overall dispersion.

Origins and Trends in Social Inequalities in Health

Health inequalities have long been the subject of demographic analysis. Changes in health disparities have important scientific, policy, and social justice implications, and demographers have recently employed the APC framework to gain insight into a number of relevant questions. One line of research, for example, applied HAPC-CCREM analyses to the repeated cross-sectional design of the National Health Interview Survey and individual-level records of mortality status to investigate

temporal trends in race/ethnic and socioeconomic differences in U.S. adult mortality rates (Masters et al., 2012). Findings revealed important race and socioeconomic disparities in recent U.S. adult mortality trends that were largely related to cohort-based changes in the population.

Another line of research employed HAPC-growth curve models on a prospective cohort design from longitudinal surveys. The models systematically examined both inter- and intracohort variation in aging-related health trajectories, and implicated both processes in the formation of social inequalities in health over the life course. The model specification is similar to that of HAPC-CCREM, except that within-individual repeated observations are now the level-1 units and the individuals are the level-2 units. Cohort membership can then be modeled as the individual-level attribute conditioning within-individual change with age. In this regard, the growth curve models have been used to test aging- versus cohort-related hypotheses. For instance, research shows strong support for the intercohort change hypothesis that posits aging trajectories of health significantly vary by birth cohort. For instance, more recent cohorts showed higher mean levels of physical functioning and self-assessments of health (Yang and Lee, 2009) and experienced slower increments in frailty with age (Yang and Lee, 2010). Conversely, there is no strong support for the intracohort heterogeneity hypothesis. That is, several lines of research have repeatedly shown health inequalities to persist across the life course after conditioning on cohort membership. Such findings suggest little within-cohort variation in health-related aging processes. However, birth cohorts differ substantially in within-cohort inequalities in aging trajectories. For example, it was found that racial gaps in frailty converged with age only in the oldest cohort born before 1924 but remained constant in other cohorts, and socioeconomic status (SES) disparities in frailty either diverged or converged depending on indicators used and cohorts under study (Yang and Lee, 2010).

Together with other recent studies on aging and social inequalities in health, the newly emerged research above has illustrated the relevance of cohorts' disparate exposures to biological and sociohistorical contexts to our understanding contemporary inequalities in health and longevity. We, therefore, strongly encourage researchers concerned with health inequalities to incorporate cohort considerations into their models and/or formally adopt cohort analysis to better understand current patterns of and temporal trends in social inequalities in a wide-range of health outcomes.

Overall Dispersion: Between-Group and Within-Group Variance

We know that varying gender, race, and SES inequalities across the life course, birth cohorts, and time periods conceivably contribute to overall inequality across these temporal dimensions. An extension to the HAPC models is to combine them with the variance function regression (VFR), which can facilitate the study of both between-group inequality (i.e., variations in the conditional mean of an outcome) and within-group inequality (i.e., variations in the conditional variance or dispersion of an outcome). As exposited in Zheng et al. (2011), the core idea of the HAPC-VFR model is to estimate mixed effects regressions for the two equations in the VFR model, whereby the first mixed effects regression models how age, period, and cohort affected mean estimates of an outcome net of individual-level covariates (sex, race, education, etc.). The second regression models how within-group disparities changed across the three temporal dimensions. Applying the HAPC-VFR to measures of self-rated health in the National Health Interview Survey data, Zheng and colleagues found that changes in health disparities in the last two decades have predominantly reflected cohort processes over period processes. The findings are consistent with the studies summarized above on other health outcomes, lending additional support for the cohort perspective on health disparities. And compared to the studies we mentioned above that focused on changes in health inequality defined by specific aspects of social stratification system such as sex, race, and SES, the HAPC-VFR model offers an analytic tool to encapsulate the general dispersion of health across age, period, and cohort. This additional information provides the basis for further research to examine the contribution to the overall dispersion by each specific subpopulation.

Inequality or disparity in statuses occurs in many domains of population processes and social life. The HAPC-VFR model provides a powerful framework and lens through which to identify and study the temporal evolution of variations in any given outcome. Therefore, the model should be broadly applicable to the study of population heterogeneity in many different substantive contexts.

Cohort Variation in Associational Studies

We finish by briefly reiterating the importance of considering cohorts' disparate exposures to biological and sociohistorical contexts when investigating demographic outcomes, even in cases wherein the outcome of interest does exhibit significant cohort-based variation. That is, cohort analysis is not only useful to demonstrate trends in certain outcomes themselves, but also useful as an explanatory factor for the associations between other variables. To highlight an historical case, the Jones Criteria in 1942 was a period-based introduction to health knowledge and technology, wherein Jones advanced an approach to identifying strep throat and administering the use of Penicillin to prevent the subsequent onset of rheumatic fever. This is a classic example of a period-based intervention of health technology to immediately improve population health. Two points, however, are especially worth noting that made the Jones Criteria an important cohort-based intervention as well. First, the age group most susceptible to the emergence of rheumatic fever is between 5 and 15 years of age. Second, rheumatic heart disease later in life has been shown to be directly influenced by rheumatic fever early in life. Thus, cohort-specific rates of rheumatic heart disease overwhelmingly reflected cases of rheumatic fever among these same cohorts early in their lives. As a result of the Jones Criteria, the immediate reduction of rheumatic fever across the 1940s and 1950s directly led to subsequent reductions in case of rheumatic heart disease several decades later. Moreover, it was largely in those cohorts that were born after the implementation of the Jones Criteria that fully benefited from. Those cohorts that

had already aged out of the most critical age range (5 to 15) had already been 'scarred' by their experiences with rheumatic fever, and thus didn't reap the full, long-term benefits of the period-based intervention.

A contemporary example of cohort processes indirectly shaping mortality trends is Lynch's (2003, 2006) and Masters et al.'s (2012) work showing recent educational differences in U.S. self-rated health (Lynch, 2003, 2006) and mortality risk (Masters et al., 2012) to be significantly influenced by, first, cohort changes in early life survival and, second, cohort changes in the qualitative meaning of education. That is, changes in early life survival across the twentieth century have made the adult environment relatively more important in shaping U.S. longevity. This, in turn, coupled with the educational revolution across the twentieth century has made socioeconomic resources more important in navigating the adult environment. Together, both processes help to fuel the observed increases in education-based health disparities in the United States.

In conclusion, research to date utilizing period and cohort analysis has gone well beyond the model identification problem, which was a major obstacle and point of contention in the field in the 1980s. New ways of conceptualizing the research problems, new techniques for analyzing these problems, and the collection and availability of superior data sources, set the stage for a new era of period and cohort analysis. We hope this emerging era will enhance our understanding of the complex interplay of human life course, social and epidemiologic conditions, and historical events and technological advances that shape demographic processes.

Person and Self: Philosophical Aspects

Alessandro Ferrara, Università di Roma Tor Vergata, Roma, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A brief historical reconstruction of the shifting meanings of the two terms 'person' and 'self' is offered. Then four specific challenges are highlighted, to which all conceptions of person or self must somehow respond: (1) What accounts for identity over time? (2) Is self-consciousness an inborn capacity or the product of socialization and recognition? (3) Is the person or self a unified source of agency or a decentered field of forces? (4) Is there continuity or radical discontinuity between persons and animals or machines?

Finally, a contrastive account of major conceptions of authenticity of the self or person is outlined.

Few terms like 'person' and 'self' in the course of history have proven to be more difficult to pin down to a univocal meaning. Furthermore, both are among the terms of most common usage, yet their exact meaning can prove quite elusive. More than offering an exhaustive definition and an exhaustive reconstruction of the history of the notions of 'person' and 'self,' it is sensible to attempt here to offer an account of the scope of variation in their usage as well as an account of the different problems that different authors and traditions have associated with them.

Person and Self Contrasted

To complicate things further, there is no settled account of the relation *between* 'person' and 'self.' The term 'person' has for a long time been the prevailing one for referring to a single human being. The onset of modernity marks the beginning of its relative obsolescence and its gradual replacement by the term 'self,' and sometimes 'individual,' at the center of the debates within the social sciences and social and political philosophy. Over the past few centuries, the term 'person' has almost disappeared from the vocabulary of the social sciences, only to undergo a sort of revival, sometimes tinged with religious overtones, in the existentialist and so-called personalist philosophical currents of the twentieth century, both religiously oriented and secular. Modern social theory has rather operated with the notion of the individual since the time of Hobbes and Locke; and then later, starting with Cooley's and Mead's symbolic interactionist perspective, it has widely adopted the concept of the self. Today a further evolution is perhaps underway: the concept of the person is regaining center stage. From Renouvier's (1903) contribution to Maritain's and Mounier's diverse versions of personalism at mid-twentieth century, the notion of the person has become pivotal in a number of more specialized fields of inquiry. In the political philosophy of the late twentieth century, for example, in *Political Liberalism* John Rawls had based his view of liberalism on a political conception of the *person*, not of the self or of the individual, in order to signal his taking distance from the traditional 'atomistic' orientation of liberalism. In order to grasp these vicissitudes of the two terms, one has to look at some of the main turning points in their evolution.

Etymologically, the term 'person' originated at the crossroads of the ancient Greek and Roman civilizations. In ancient Greek, *prós-opon* (literally 'placed in front') designated the artificial face, the mask that actors used to wear on stage when performing tragedies. The Latin verb *personare* also alluded to the realm of the performing arts: it meant to 'sound through,' to let the voice reach out to the watching and listening public through the mask. Metaphorically, then, in its origins the term person carries a trace of the willful appearance for the sake of others. But the Roman civilization also grafted a *legal* connotation on the term 'person': the legal person was another sort of mask, the individual human being in her capacity as bearer or rights, privileges, prerogatives, but also duties and obligations. In that sense, to be a self without being a legal person would be tantamount to being nothing. Typically, in these public minded cultures the sphere of the private was designated by terms such as *idiotes* and *privatus*, both of which carried a diminishing connotation – they presupposed that something was somehow missing.

Sometime during the Hellenistic period and at the apex of the Imperial Age, a shift of meaning began to occur. The increase in complexity and the somewhat more anomic quality taken by social life in the Hellenistic monarchies and in Imperial Rome, the increase in complexity of the political apparatus alongside the more despotic and arbitrary styles of government, and the increasing religious eclecticism of the Roman public world and the appearance of the Christian ethos of holiness and personal sanctity all contributed to the rise of a cleft between *public* and *private* life and to a new distribution of value across that divide. Stoic philosophers like Seneca, Epictetus, and Marcus Aurelius on the one hand, and the early Christians on the other, were at one in regarding with suspicion what now appeared as a realm of merely public, artificial, contrived personal masks or roles. Inwardness and depth belonged to the *self*, whereas the person stood now for convention, tradition, custom, and superficial appearance. This new relation between the two terms continued to dominate throughout the Middle Ages (Augustine and Erasmus), the Renaissance, and the Reformation (Luther).

Another major shift occurred with the rise of modern political philosophy, the rise of the modern notion of rights, and the modern conception of citizenship. Whether the focus was on the capacity for autonomous reasoning or autonomous

agency, whether the human being was regarded primarily as the possessor of rationality or the bearer of inalienable rights, throughout early modernity and the Enlightenment interest was primarily directed to the human self as such – the rights were typically predicated as universal rights of 'man' as such – and the notion of the person began to look inextricably entangled with the particularism of estates and the privileges of the order of ranks typical of the absolutist monarchies. As Hannah Arendt has pointed out, the French revolutionaries had no place for the notion of the person, or thought much of the legal person as a category protected by the rule of law.

A new reversal of the connotations of these two terms takes place in the twentieth century, when the term 'person' becomes synonymous with a *nonatomistic* view of the human self. The thick web of relations of recognition that supposedly constitute the person is now understood within as diverse philosophical traditions as existentialism, Mounier's personalism, and Habermas's intersubjective view of subjectivity, as a powerful alternative to the modern atomistic self. This motif is at work in John Rawls's above-mentioned 'political conception of the person' as endowed with two moral powers, namely, the capacity to have a sense of justice and the capacity to form a conception of the good.

The Challenges of Conceiving Person and Self

Aside from the issue of their reciprocal relation and their specific difference, 'person' and 'self' refer to a single human being considered under the aspect of his or her distinctively human capacities. Here we immediately reach a point where the overlap between different conceptions ends and a host of problems arises to which different solutions are offered, which distribute without a clear pattern across the usage of the two terms.

Identity over Time

The first issue on which different conceptions of the self and the person diverge concerns identity over time. What allows us to consider a person or self that obviously undergoes continuous changes over time still 'the same person'? In what sense as 50 year olds are we still the same person as the 20 year old of decades ago? We can contrast four different answers to this question. The first answer, typical of ancient and medieval philosophy, links identity over time with the sameness of an (differently conceived) essence – a personal essence underlying also the body – which manifests itself through the changes undergone by the person or self (Plato, Aristotle, Augustine, and Aquinas). The second position connects identity with the psychological continuity of its possessor: it is *memory* and not the physical continuity of the body that allows us to consider the person of 50 years the same as the 20 year old she once was (Locke). The third answer is Hume's and Parfit's answer: psychological continuity is largely an illusory attribution of an identity, on the part of a mental agency, to episodes that only in a vague sense are similar and related. The self or the person, so conceived, is indeed a gallery of selves and persons whose relatedness is quite tenuous and precariously maintained in the way that habits and customs are maintained. By the end of the nineteenth century, Nietzsche will give another twist to the same line of reasoning: we seek to put a construction of unity upon the diversity of our self-experiences for the sake of feeling secure and reassured. Finally, Kant's answer transforms identity into a transcendental feature inherent in all human beings.

Self-Consciousness: Inborn Capacity or Product of Socialization and Recognition?

Another bone of contention has been the nature and scope of that capacity for self-reflectiveness and self-consciousness that traditionally all conceptions of the self and of the person have presupposed. The various conceptions have polarized around two major options. One view, often called 'atomism' by its critics, takes this capacity for self-awareness as a sort of *natural* endowment of the human being. Whether because it belongs to her essence, because it is given to her as a potential of the soul, or because it emerges as a result of neurobiological processes, self-awareness and self-consciousness constitute inborn capacities that need the world only as a sounding board on which the person or self tries self-initiated action-projects and, in so doing, becomes aware of herself as a center of agency. This view comes in many versions. Augustine, Descartes, and Husserl, under different premises, all favor introspection as a privileged path to inner reality. Others, like Hume and Nietzsche, are much more skeptical about it, but all these authors share a view of the self as basically self-sufficient. Within political and social philosophy, Hobbes and Locke are the most illustrious representatives of an atomistic understanding of the self.

The other view starts from the assumption that the capacity for self-awareness is formed in the context of the person's or self's relation to the social world. Hegel and Mead from very different premises do converge on the idea that self-sufficiency vis-à-vis the world is largely an illusion, but in fact the self-awareness distinctive of personhood and selfhood emerges in the process of interacting with other persons and selves as a product of either seeking and obtaining recognition (Hegel) or learning to see oneself through the eyes of the other (Mead). From Mead's perspective, thinking becomes a special case of the activity of carrying out a conversation mediated by symbols with others: indeed, thought is best conceived as a conversation with oneself. From a quite different angle, in his thoughts on the impossibility of a private language and on the notion of following a rule, Wittgenstein also emphasizes the dependency of individuality and subjectivity on shared practices.

This divide is reproduced in almost all social sciences. Within the sociological tradition, for example, theorists such as Spencer, Pareto, Homans, and Blau understand the self of the social actor as coming to the scene of social interaction with a preformed rational capacity for reflection, whereas not just Mead and Cooley but also theorists such as Durkheim, Schutz, and Parsons understand that capacity for reflection as the inner sedimentation of processes of interaction. Within the psychoanalytic tradition, to take another example, theorists like Freud and Klein understand the capacity for ego strength and rational self-awareness as the product of internal vicissitudes of the drives, while object relations theorists such as Winnicott or self-psychologists like Kohut understand it as the product of the self's embedment in a relation with an empathic caretaker.

A Unified Source of Agency, or a Decentered Field of Forces?

These considerations lead to yet another major issue with respect to which theories of the person and of the self have taken sides. Some of these theories tend to portray the person as a more or less unified source of autonomous initiatives. Certainly what we call a person or a self contains several distinct aspects – cognitions, beliefs, desires, propensities, dispositions, capacities, virtues, and so on – but the views of authors like Plato, Aristotle, Augustine, Aquinas, Descartes, Hobbes, Locke, Kant, Hegel, and Sartre, whom we find disagreeing on other aspects, converge in depicting these aspects as being somehow hierarchically subjected to a central agency of sorts: the soul, reason, the will, and self-consciousness are all different ways in which this central agency has been identified. On the other hand, authors again as diverse as Hume, Diderot, Schopenhauer, Nietzsche, Freud, Bataille, Foucault, Goffman, Rorty, Barthes, Deleuze, and Derrida all share the suspicion that this impression of centeredness is largely illusory and the product of 'impersonal' or 'intrapersonal' forces that create it and make it a compelling appearance for the person.

Continuity and Radical Discontinuity between Persons and Animals or Machines

But what is it for a being to be a person or self, and what kind of entity can be called a person or a self? Here the opposition is between conceptions that radically sever personhood or selfhood from nonhuman forms of consciousness and conceptions that take a more nuanced view of the matter, and depict the difference in terms of a gradient of capacities. Starting from the latter, typically we find here conceptions of the person or the self that posit the capacity for representing the world, in order to then act on it, as the crucial defining ability. Humans are then singled out from the rest of beings by self-representation or self-consciousness – which belongs to them alone – but that capacity in turn is only a reflective enhancement of a representational capacity that as such can also be found, though to a lesser degree, in certain animal species and in advanced artificial intelligence machines. Over limited territories – for example, the kind of representational and practical competence involved in playing chess – machines can even outdo humans. The conceptions that introduce a more radical discontinuity between humans and nonhumans define the former basically as 'subjects of significance' (Taylor, Heidegger, and Gadamer) – beings for whom things *matter*. From their point of view, what distinguishes persons and selves from other beings capable of representation is not just a greater share of 'strategic power,' 'the capacity to deal with the same matter of concern more effectively' or a superior capacity for planning (Taylor, 1985: p. 104). The central defining feature is responsiveness, openness to certain strong evaluations, principles or values in light of which not only single action plans but even one's own life is conceived and assessed. From this standpoint, the sense of the self is the sense of where one stands in relation to this matrix of meaning. In one of its most famous versions, this view posits that as persons or selves, human beings are beings for whom their own being is a matter of concern (Heidegger).

The Person, the Self, and Fulfillment

Finally, conceptions of the person and of the self do take quite different views of what it means for a person or a self to *flourish* or to attain *authenticity*. Some conceptions understand authenticity as being primarily linked with breaking free from the constrictions of an entrenched social order. For example, some authors affiliated to aesthetic modernism (Baudelaire) or to *Lebensphilosophie* (notably Nietzsche) tend to understand authenticity as something to be attained '*in opposition* to the demands of society' and of culture, whereas in the writings of authors such as Rousseau, Schiller, Herder, Kierkegaard, and others we find a recognition (with very different degrees of awareness and explicitness) of the fact that social expectations, roles, and institutions cannot merely be understood as playing a constraining, 'disciplinary' or repressive role but also somehow constitute the symbolic material out of which fulfillment can be generated. In the psychological realm, too, we find representatives of these two versions of authenticity. Laing's understandings of schizophrenia as a response to the imposition of an inauthentic life and of 'madness' as resistance to the irregimentation of mental life, and Lacan's understanding of the unconscious, are views of the first kind. On the other hand, Kohut's psychology of the self and Winnicott's notions of 'creative living' and of the 'true self' are the most obvious representatives of an integrative understanding of authenticity within the psychoanalytic tradition.

From another point of view, we can contrast coherence-oriented and decentered views of authenticity. Far from considering fulfilled a life course that can be summed up as a coherent narrative, some consider *narratability* as the epitome of failure. In his reflections on the notion of 'limit-experience,' for example, Foucault, continuing a tradition that he associates with the names of Nietzsche and Bataille, equates the paradigmatic kind of fulfilled subjectivity with the one undergoing a 'limit-experience.' From a variety of *lebensphilosophisch*, aesthetic modernist, poststructuralist, therapeutic, and postmodernist vocabularies, the advocates of a *decentered* understanding of authenticity oppose all attempts to restore an internal hierarchy between what is central and what is peripheral to a life project, a personality, or an identity. By contrast, all authors who propound a *centered* notion of authenticity do wish (1) to maintain some kind of orderly stratification of the layers of an identity, (2) to continue to speak of a core and a periphery, and (3) to make sense of the plurality of experiences, detours, and side narratives to a life history as variations on a unique theme.

Finally, we can contrast *consequentialist* and *exemplary* views of fulfillment. According to the former (what Ronald Dworkin has called the 'model of impact'), a person's life is all the more fulfilling the greater its impact on the external world, or the larger the difference it has made. Hegel and Marx certainly share such a view. For both of them, the full flourishing of a person's life is connected with the person's objective contribution to advancing a differently conceived historical process in which the person is immersed. According to the exemplary view (called by Dworkin the 'model of challenge'), the measure of fulfillment is provided by success in meeting a challenge that carries a unique significance for the person, independently of the impact of such success on the external world. Rousseau and

Kierkegaard offer representative versions of such a view. For both of them, the full flourishing of a person's life is connected with the person's capacity to reconcile 'being and appearance' (Rousseau) or to 'choose her personality' (Kierkegaard), in other words to bring outer conduct and deeper inner motives into alignment.

Concluding Remark

To conclude this review of the ways in which the person and the self have been conceived, there could not be a sillier question to raise then 'Which of these views comes closest to grasping the reality of the human self or the person?' For these views are in a way not to be understood as representations of an independent reality in the empiricist sense of the word – a realm of facts about the constitution of the human being that we may grasp or fail to grasp. Rather, they are to be seen as competing vocabularies, as alternative types of lenses – indeed, as sets of premises – which we use in order to make sense of something as crucial for our experience of the world as the idea of personhood. Evidence for and against each of them can be and certainly is usually considered, but is unlikely to be ultimately decisive. Ultimately decisive has generally been our sense of the contribution that adopting one or the other can give to shaping an overall view of the world in which we find reflected what most matters to us.

Person Perception, Accuracy of

David C Funder, University of California, Riverside, Riverside, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The accuracy of person perception concerns the connection between judgments people make of the psychological attributes of others, usually personality traits, and the actual status of those attributes in the people who are judged. Such judgments are correct roughly two times out of three and the degree of accuracy likely to be attained depends upon four moderator variables: properties of the judge, the target, the trait that is judged, and the information upon which the judgment is based.

The *accuracy* of person perception (also called *personality judgment*) refers to the connection between judgments people make of the psychological attributes of others and the actual status of those attributes in the persons who are judged. The psychological attributes may be another person's personality traits, or his or her thoughts and feelings at a given moment. The ability to judge personality has concerned psychological researchers, off and on, for more than a half century (see Allport, 1937; Funder, 1999; Kenny, 1994). The ability to guess what someone is thinking and feeling, called *empathic accuracy*, is a newer topic that is receiving increasing attention (Rollings et al., 2011). Research on either topic entails special difficulties because the notion of 'accuracy' raises thorny questions concerning how accuracy is to be conceptualized and evaluated. Despite these difficulties, research since 1980 can report important empirical and theoretical progress.

The Importance of Accuracy

The accuracy of person perception has obvious practical importance. Employers and other people in everyday life rely heavily on their perceptions of other persons' attributes such conscientiousness, intelligence, friendliness, dominance, and many others. It is an everyday occurrence to make decisions concerning other people as a function of beliefs about what those people are like. Moreover, clinical assessment typically relies heavily on the impressions of a psychiatrist or psychologist concerning a person of interest (Block, 2008). Interpersonal judgments and sociometric ratings are also often used as data for psychological research. The accuracy of these perceptions is critical for the quality of the data and the research that is based on them.

The accuracy of personality judgment is also important for theoretical reasons. Accurate person perception implies knowledge about the connections between observable behaviors, on the one hand, and personality traits, on the other hand. Thus, to understand the accuracy of person perception would be to understand the ways in which personality affects behavior. Person perception is a traditional topic of social psychology (*see* Social Psychology) and the connections between personality and behavior are traditionally studied by personality psychology (*see* Personality Psychology). The topic of accuracy in person perception transcends the boundaries between these traditionally separate subfields of research.

Finally, the oldest topic in philosophy, and one of humankind's most ancient concerns, is the relationship between perception and reality. Research on the accuracy of person perception is driven by curiosity concerning just this issue.

Difficulties in Accuracy Research

In the light of the importance of the accuracy of person perception, it may be surprising to learn that researchers have neglected the topic for long periods of time (e.g., the years 1955–85), and some psychologists with relevant interests (e.g., in person perception) continue to shy away. This avoidance has been caused by several considerations. The most important consideration is the topic's inherent difficulty. At a general level, the topic of accuracy is difficult to conceptualize or to operationalize, because it requires the development of some criterion by which interpersonal judgments can be evaluated as right or wrong. Some psychologists have considered the development of such criteria to be either impossibly difficult or in principle impossible, and therefore turned their attention to other topics. At a more specific level, an important series of articles by Lee Cronbach (e.g., 1955) revealed complex and hitherto-unsuspected technical difficulties inherent in evaluating accuracy in terms of agreement among different judges. Rather than leading to improved methods, this article and related critiques managed to shut down a then-lively field of research, and appeared to intimidate a subsequent generation of researchers from addressing the topic (see Funder, 1999). A further obstacle to accuracy research was the widespread influence of a set of attitudes that seemed to discourage interest in the topic. The 'person–situation debate' in personality psychology (Kenrick and Funder, 1988) led many researchers to believe that the connections between personality and behavior were few and weak. If this were true, it would make little sense to attempt to investigate the accuracy of person perception. At about the same time, the increasing popularity of research on 'errors' in person perception led to a widespread belief that human judgment is characteristically, even fundamentally mistaken. If this were true, investigations of accuracy would seem to hold little hope.

Resolving the Difficulties in Accuracy Research

Research on accuracy was able to move forward only after these difficulties began to be resolved.

First, views concerning the existence and importance of personality traits, and the abilities of human judgment, began to change during the 1980s. The person–situation debate was resolved as reiterating the importance of stable attributes of personality (Kenrick and Funder, 1988). Research on the errors of human judgment was reinterpreted in a broader context in which it was less often seen as implying that human judgment is always or fundamentally wrong (e.g., Swann, 1984). Studies of error identify important shortcuts ('heuristics') and other processes of human cognition. However, they do not imply that judgment is inept, because the processes that produce errors in the laboratory often lead to correct judgments in real life. Moreover, research on error is fundamentally limited because it can illuminate only how judgments fail to achieve perfection, rather than how correct judgments are ever achieved (Krueger and Funder, 2004). The methodological issues identified by Cronbach and others also received a reexamination during the 1980s. This reexamination yielded more sophisticated analytic techniques that allowed the methodological complications to be bypassed or specifically incorporated into analytic designs. David Kenny's 'Social Relations Model,' a data-analytic technique that accounts for effects of judge, target, and their interaction on interjudge agreement, was an important breakthrough in this regard (Kenny, 1994).

The Realistic Conceptualization of Accuracy

Historically, the thorniest issue in accuracy research has been the criterion problem. By what standard can a judgment of personality be evaluated as right or wrong? The answer to this question depends on how accuracy is conceptualized.

Although alternative conceptualizations have been proposed, current research on the accuracy of personality judgment is generally based on a *realistic* approach, consistent with the writings of Egon Brunswik (1956). The approach assumes that psychological attributes of people really exist, though they are only probabilistically knowable through cues of uncertain validity (Funder, 1995). The real nature of a person must then be ascertained, as well as possible but always with less-than-certain validity, through multiple sources of evidence including the person's self-judgment, judgments by others, and his or her relevant behavior. The index of whether a judgment is accurate, in this view, is the degree to which it converges with these multiple criteria.

The Degree of Accuracy

When research on accuracy in person perception revived during the early 1980s, one of its first orders of business was to dispel the impression left by research on error, that human social judgment is always or fundamentally mistaken.

A large number of studies documented the accuracy of personality judgment in two ways. The most common method was to show that different judgments of the same person tend to agree. Research examined self–other agreement and agreement among judges and found that significant agreement was the rule rather than the exception across a wide band of personality traits, even after brief periods of acquaintance. Evidence concerning the ability of personality judgments to predict behavior is more difficult to gather and therefore was slower in coming, but eventually showed that layperson's personality judgments have an impressive ability to predict independent observations of an individual's behavior (Funder, 1999).

The overall degree of accuracy in person perception is difficult to characterize, because it depends upon a number of factors including the ability of the judge, the judgability of the target, the trait that is judged, and the amount and kind of acquaintance between target and judge (see next section). But while it is for these reasons an oversimplification, it is also a fair characterization to state that the usual correlation among criteria for accuracy is in the range 0.30–0.40. This translates to the statement that one person's perception of the personality of another is correct roughly two times out of three.

Moderators of Accuracy

Research since 1980 has found that the degree of accuracy in person perception depends upon four moderator variables.

The Good Judge

The search for the 'good judge of personality' is one of the oldest concerns in the accuracy literature. This search motivated many investigators during the 1930s to 1950s and it was their failure to find consistent results that contributed to the three-decade hiatus that followed. Part of the reason for this failure may be the presence of methodological flaws in many early studies, and another part may be that individual differences are not very large because personality judgment is an essential social skill. The typical person is described in positive terms, and so people who describe others favorably tend to be more accurate – curmudgeons are usually wrong. Perhaps for this reason, good judges of personality are generally described by others as pleasant, happy, and easy to be with (Letzring, 2008).

The Good Target

As Gordon Allport noted years ago, some people are relatively open books whereas others are difficult to understand even after years of acquaintance. According to research by Colvin (1993), the judgable person is one who has an integrated, well-adjusted personality. The consistency among such a person's actions, thoughts, and personality leads them to be coherent overall, and relatively easy to judge. Moreover, most people can accurately identify who, at first acquaintance, they can judge most accurately (Biesanz et al., 2011).

The Good Trait

Traits differ strongly in their judgability. Relatively observable traits, like sociability and talkativeness, are much easier to

judge accurately than more hidden traits like ruminativeness and anxiety. Some evidence also suggests that traits that are extremely desirable or undesirable to possess are more difficult to judge accurately than traits more neutral in evaluative connotation. Vazire's self–other knowledge asymmetry model theorizes that less visible traits should be judged more accurately by the self, whereas highly desirable or undesirable traits should be judged more accurately by others (Vazire, 2010).

Information

The accuracy of a judgment also depends critically upon the information upon which it is based. The information variable has two facets, quantity and quality.

The quantity variable pertains to the *acquaintance effect*, the tendency to judge someone more accurately the longer one has known him or her. The straightforward expectation would be that more information is likely to produce more accurate judgment, an expectation that has been repeatedly confirmed. The quality variable pertains to the kind of context in which one person observes another. Even holding amount of acquaintance constant, different contexts may produce different degrees of accuracy (Letzring et al., 2006).

Theoretical Development

Several theories describe how accurate judgments come about. One theory, Kenny's 'PERSON' model, conceptualizes personality judgments as the result of multiple influences including the judge's response proclivities, his or her knowledge of people in general, the actual personality of the target, and other factors. Another theory is Funder's Realistic Accuracy Model (RAM, Funder, 1995). RAM conceptualizes an accurate personality judgment as the result of a process that begins with the target emitting relevant information (e.g., performing a relevant behavior), which then must become available to a judge, who then detects it and utilizes it correctly in reaching an accurate judgment. Both the PERSON and RAM models can be used to rationalize the moderators of accuracy that have been found to date, and suggest new ones for investigation in future research.

Conclusion

The accuracy of person perception is an important topic that, after periods of neglect, has become a mature field of research and a mainstream concern of personality and social psychology, which is becoming even more important in the twenty-first century.

Personal Identity: Philosophical Aspects

Gertrud Nunner-Winkler, University of Munich; Max Planck Institute for Human Cognitive and Brain Sciences, Munich, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The two main classes of philosophical theories of numerical identity are described: substance-based theories focus on the soul, body, and brain, and relational theories on psychological continuity and connectedness. Social science analyses deal with the subjective sense of identity. Postmodern theories renounce the unity of the person. Modern theories assume its indispensability, yet differ in the grounding of identity, the mechanisms stipulated for stabilizing identity, and the description of the stances that actors take toward themselves. Empirical data are presented that support the value commitment model of identity stabilization.

Identity has two meanings: it denotes category membership (e.g., X is a man), or it refers to a specific individual (e.g., X is Mr. A). Goffman (1963) refers to the former as social and to the latter as personal identity. Personal identity is synonymous with numerical identity. There are formal properties of the concept of identity, reflexivity, and congruence, which are not relevant to the practical problem of verifying the truth of statements such as 'A and B are the same person.' This requires material conditions of correctness and a clear explanation of the way the terms 'same' and 'person' are used (Garrett, 1998).

Personal identity is highly relevant to practical issues – to moral as well as self-regarding prudential concerns, for example 'Is A the wanted murderer?', 'Does a relation of personal identity obtain between the fetus that B once was and B as an adult (e.g., can B as an adult claim compensation for a medical malpractice she suffered as a fetus?)?' If this is so: 'Is abortion justifiable?', 'Are my brain transplant and I the same person?', 'On noticing the onset of Alzheimer – can I issue an advanced directive to abstain from life-saving measures, thus binding my later totally Alzheimer-stricken self who might desire to keep on living?', 'What about immortality?' (Shoemaker, 2012).

Numerical identity concerns objects as well as persons. Persons are objects – they have material bodies that are located at specific space–time points. But whereas the identity of objects can be judged only from an external or third-person perspective, persons have an internal or first-person perspective as well. From this internal perspective, the identity question attains an additional meaning: 'Do I experience to be the same person today as I was yesterday?' This pertains to the 'sense of identity' which can be based on the same criteria used to determine someone else's identity. But for sociostructural reasons discussed later in this article, identity criteria applied from an external perspective and those from an internal perspective increasingly come to diverge.

In the following, I will first present different approaches to personal identity (Section Personal Identity Theories), compare them, and discuss differing meanings of the core terms 'person' and 'same' (Section Some Interim Considerations). In the second part, I will describe several theories dealing with the sense of identity (Section Sense of Identity Theories), then present some relevant empirical data and discuss their implications for sense of identity theories (Section Sense of Identity – Some Empirical Findings).

Personal Identity Theories

Theories of personal identity can be divided into two main classes with each of them divided into further subcategories. Substance-based theories are immaterialist (soul) or materialist (body and brain). Relational theories refer to psychological continuity or hold the 'identity does not matter' view.

Substance-Based Theories

Immaterialist Theories

Dualist approaches assume that persons are composed of two entities – body and mind – which are only contingently related to each other. Thus, Plato maintained that persons are essentially immaterial souls and therefore will survive death and the destruction of their bodies. Christian creed, too, implies that mortal flesh and eternal soul are separable. Also, beliefs in reincarnation or in an immersion in some transcendental consciousness assume an ego substance that is present at any stage of life and even after one's current life has ended. Today, dualist assumptions are referred to as the Cartesian ego view since it was Descartes who had anchored the only truth beyond doubt in our thinking, thus specifying mental activity as the essence of personhood.

Several objections have been raised against the dualist claim. (1) It provides no answer to the mind–body problem. Descartes' mechanistic conceptualization of the mind as an inner ghost operating a body understood as an automat or clockwork is no longer tenable. Modern brain sciences have shown that neither emotions nor complex thinking processes are separable from the structure and functioning of the biological organism (Singer, 2002; Roth, 2003). (2) The concept of a soul does not unequivocally solve the problem of numerical identity – especially beliefs about reincarnation or immersion disregard the issue of individualized existences. (3) Souls are unobservable. The assumption that they extend over time and have more than a momentary existence rather than being continuously exchanged cannot be verified (Perry, 1978). Finally, (4) the belief in unobservable souls does not meet the practical concerns underlying the debate of identity.

Such objections do not refute dualism. Its metaphysical assumptions withstand empirical verification. This shows that criteria for the nature of persons and evidence for personhood

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63057-X

may diverge. In any case, modern philosophical debates pay little attention to dualistic positions.

Materialist Theories

On the body theory, a person is identical to a living human body. Persons exist as long as their bodies exist, and identity is guaranteed by sameness of body. Sameness allows the gradual replacement of matter that is functionally absorbed. The paradox of Theseus' ship illustrates the basic idea: "The planks of the ship corrode and gradually are replaced; the old planks are piled up in a shed. Finally all planks are exchanged. What is Theseus' ship – the renovated ship in the harbor or the pile of original planks stored in the shed?" Consistently, the renovated ship is considered Theseus' ship: despite exchanged materials, it conserves continuity of form and function over time.

In the normal case, same body and same person coincide. Yet in thought, experiments philosophers seek to disentangle variables. 'Brain transplant' devises the following situation: 'A's body is devastated in an accident, and B's brain destroyed by a tumor. A skillful surgeon succeeds in putting A's brain in B's body. Is the resulting person A or B?' Most would agree: the survivor is A – the person is where the brain is. A further thought experiment – 'Bionic replacement' – tests for acceptance of matter exchange: 'Cancer is disintegrating A's brain. A new technology allows gradually replacing A's brain by silicon parts. Finally, A ends up with an entirely bionic brain. Is postoperative A the same person he was before?' Again, agreement is assumed: the new brain is continuous with and serves the same function as the old one (i.e., it will sustain self-conscious mental life distinctive of the person). This answer marks a transition to relational theories. But first some objections to equating brain and identity will be presented.

These objections are as follows: (1) as noted above, emotions are psychophysiological processes (i.e., they essentially involve the body); (2) long-term stress or intense traumata are stored in a bodily memory and can produce permanent bodily disorders, and healings attained in psychosomatic medicine and trauma therapies evidence that body and mind are inseparably intertwined; and (3) early childhood experiences that happened before conscious memory functions have evolved are stored in the body (Buchholz, 2010). Altogether, exchanging bodies may well jeopardize identity.

Relational Theories

Psychological Continuity

John Locke (1632–1704) rejected the assumption that some substance is necessary for the retention of one's identity. He defined person as a thinking and intelligent being with reason and reflection whose identity reaches as far as his consciousness extends backward to past actions or thoughts (i.e., I am the same today as yesterday if I remember having had an experience as that person). Thus, the core criterion of identity is memory, a psychological relation connecting temporally distinct person stages.

Already his peers voiced objections. First, memory fades. Thomas Reid (1710–96) gives an example: a 40-year-old officer stealing the enemy's standard recalls stealing apples from the neighbor's orchard. As an old man, he remembers stealing the standard, but not stealing the apples. On Locke's account, the officer would have to be both identical to the apple-stealer (because of the transitivity relation that identity implies) and not identical to the apple-stealer (because he has no direct memory of the boy's experience). Second, Joseph Butler (1692–1752) notes that rather than constituting identity, memory presupposes identity, for I can only remember experiences as my own if I have a self-understanding. Remedies have been suggested. Chains of overlapping memories are substituted for the more rigorous requirement of direct memory continuity. And Locke's criterion of memory has been extended to include other psychological aspects (e.g., beliefs, goals, desires, and resemblance of character). In short, personal identity is taken to be constituted by psychological continuity.

Identity Does Not Matter

Parfit (1982; 1995) distends the conceptual strategy of equating personal identity with psychological continuity. He argues from the thought experiment 'fission': "My brain hemispheres are functional duplicates of each other. They are transplanted into the bodies of my two triplet brothers. After the transplantation both are psychologically continuous with me – they are both me. What has happened to me? I cannot be both and there exists no non-arbitrary criterion for deciding among the two. The only option left is: I do not survive. Yet this differs from normal death. The survivors seem to remember my thoughts and experiences, will have the same beliefs and desires, they will realize my intentions and their character will be like mine – in fact it will almost be as if I had survived." Parfit concludes: What matters for practical concerns is not identity but psychological connectedness. This relation to my replica contains all that matters – even though they are not me. Hence, my special concern for their future is not annulled. But what is normally understood as a self-interested prudential concern is now turned into a moral obligation – the obligation to care for others.

Some Interim Considerations

Comparing the Different Identity Theories

Exclusive Positions

Some theories assume only one constitutive criterion. (1) Immaterialist positions assert that persons essentially are souls. This belief, however, cannot be empirically verified. (2) Materialist positions maintain that persons are essentially biological organisms. This allows imputing numerical identity between a patient in a permanent vegetative state (PVS) and the adult, infant, or fetus he once was. It disagrees, however, with common responses to thought experiments like brain transplant. (3) Relational theories hold that persons are essentially conscious minds. This claim does not, however, accommodate the inseparability of body and mind noted above. (4) The identity does not matter view, too, neglects body-based aspects of persons. In fact, the easy acceptance of the brain solution in the transplant cases might reflect latent dualist preconceptions still prevalent in our everyday thinking habits.

Composite Positions

Some positions assume that persons require both body and mind, yet differ in the relative weight attributed to physical

versus psychological criteria. (1) The claim that the body criterion is more fundamental is backed by pointing to its greater usefulness in determining numerical identity: it is more extensive (the person is present whenever the body is there) and more varied (there are more and more reliable ways of determining physical sameness, e.g., direct and genetic fingerprints, blood tests, photographs, and witnesses) (Penelhum, 1972). (2) Some authors deem psychological criteria as more important. They see persons as constituted by consciousness. Body and brain are necessary to sustain mental life, yet this cannot be reduced to material conditions: Although I am made of matter, I am distinct from my body and brain (Garrett, 1998). Although biological continuity preserves continuity over time, it is the relation of psychological continuity that grounds our practical concerns (Shoemaker, 2012). These considerations show that criteria for the nature of persons and for determining sameness over time may diverge.

Renouncing a Univocal Identity Concept

Locke declared 'person' a 'forensic' term, a moral and legal concept denoting a responsible agent endowed with rights and duties. This understanding is highly relevant to many ethical issues. However, as Shoemaker suggests, there is no guarantee that there is one single correct conceptualization: "Why not think that some practical concerns bear a relation to one criterion or sense of identity, while other practical concerns bear a relation to a different criterion or sense of identity" (2012: 39). Thus, the biological criterion grounds claims to being compensated as an adult for what happened to him as a fetus. In contrast, signing advanced directives relies on psychological criteria. Also, the differing definitions of death in use hinge on different criteria for personal identity: the 'higher brain standard' according to which death occurs at the point of irreversible loss of the capacity of consciousness is based on psychological criteria, whereas the actual practice of medicating PVSs relies upon the biological criterion – death occurs when the organism dies.

Different Uses of the Basic Terms

Same

The word 'same' is used in a comparative and a numerical sense. In the comparative sense, "'same' if applied to two distinct things … means 'alike' and, if applied to one thing at different times … means 'unaltered' … (In) the numerical sense, in which two things are said to be the same are said not to be two, but one" (Penelhum, 1972: 99). These two senses correspond to different meanings of the identity question – the reidentification and the characterization question. Reidentification allows for a multitude of 'normal' changes. Thus, the fetus can easily be numerically identified with the grown adult and the demented patient if there is bodily continuity that is independently verifiable by various tests. What are considered 'normal' changes depend, of course, upon the way the object under scrutiny is conceptualized. A gold statue and the lump into which it is transformed when melted are the same if analyzed in terms of matter (e.g., in terms of the chemical properties of gold). They are not the same if considered in terms of a piece of art (Garrett, 1998). Analogously, attesting sameness of a person depends upon what 'person' is taken to mean.

Person

The term 'person' (cf. Danto, 1972; Bohlken, 2009) may refer to any human being, just as the word 'thing' refers to any object whatsoever. In fact, 'person' often is contrasted with 'thing' in order to point to the special treatment that human beings deserve (i.e., never to be used merely as a means) (Kant, 1959/1787). In a more restricted sense, 'person' specifies a legal term denoting a being with rights and duties held to be accountable. By implication, not all human beings are legally persons (e.g., children and idiots), and not all legal persons are human beings (e.g., a cooperation considered a juridical person). Equating person with accountability marks self-awareness and rationality as constitutive for personhood.

Substance-based theories equalize 'person' with some essential entity – the soul, body, or brain – which warrants identity across time. Relational theories refer to psychological features – memory, beliefs, desires, and similarity of character – thus denoting a specific state or phase of human beings. Infants, fully demented individuals, or PVSs are not considered persons. Both approaches, however, draw on criteria that can be ascribed from a third-person perspective for determining numerical identity. In contrast, theories of a sense of identity take a first-person perspective for dealing with the question: How do individuals achieve and stabilize a sense of inner unity and sameness?

Sense of Identity Theories

In the social sciences, this question has become topical. Thus, just in psychology the number of identity-related publications rose from about 8000 to almost 22 000 between 1984 and 1993 (Ashmore and Jussim, 1997: 5). There are sociostructural reasons for this heightened interest. In traditional societies, criteria determining social as well as personal identity converged across contexts, life cycles, and perspectives. To illustrate, the identification of X as 'tenant of the Z farm' simultaneously denotes X's social (e.g., man and farmer) and personal identities (e.g., the stout man living at the south end of the village). These identity markers are valid in all contexts (in his family, the village, and the pub, everybody knows him as the stout man running the Z farm) and across his life span (from birth to death, he is linked to the Z farm as its future, present, or former tenant). And descriptions from first- and third-person perspectives agree: his farmhands, wife, and other villagers know him as the tenant of Z, and he himself identifies with this attribution – in fact, so much so that he will have inscribed his tombstone, 'Here lies the tenant of Z farm.' With modernization, these dimensions diverge. With urbanization, social and personal identities separate: townspeople can only vaguely guess each other's social identity, let alone know their personal identity. Social differentiation and cultural pluralization produce consistency problems: individuals partake in diverse subsystems or subcultures, each operating according to their own code (Luhmann, 1985) or claiming specific values. Thus, across different contexts they often face contradictory expectations. And rapid social change jeopardizes experiencing personal continuity over the life course. From a third-person perspective, this is unproblematic. Members of modern societies are used to ignoring each other as strangers. When

someone's identity needs to be known, there are mechanisms for determining social identity (e.g., titles and uniforms) and personal identity (e.g., passport, genetic analysis, and witnesses). Problems may, however, arise from a first-person perspective: "Am I a unitary person – given I act so differently as a father, manager, and church member?" "Am I still the same person I was – after I changed my job, left the church, and got divorced?" Reference to unparalleled fingerprints does not help – individuals do not conceive of themselves in terms of physical markers.

Theories addressing this problem diverge. The main split concerns acceptance or rejection of the modern identity concept based on the criteria advanced by Erikson – consistency across situations and continuity across one's life cycle. Postmodernists claim that there is no consistent self. Others adhere to the modern concept, yet differ in the way they see identity grounded, in the mechanisms they assume will stabilize identity, and in the way they describe the stance that agents take toward themselves.

Postmodern Approaches

There are precursors to today's questioning of consistency and continuity. Thus, Montaigne (1533–92) notes: The self is "unstable and fluctuating from one minute to the next" (2005: 296). Hume (1711–76), too, attacks the spiritual-substance assumption of a unique and simple self. People are "a bundle or collection of different perceptions." Given their constant changes, identity does not exist.

Postmodern authors agree. The classical requirements of reliability and constancy no longer match modern living conditions (Gergen, 1990). These necessitate "a mindset able to leave contradictions and not dominated by an obsessive need for identity" (Keupp, 1997: 17). New constructs are invented, for example, 'tinker mentality' (Gross, 1985), 'patchwork identity' (Keupp, 1988), 'the plural subject' (Welsch, 1993), and 'identity as collage' (Pazzini, 1986). Such revisions are influenced by French poststructuralists debunking classical views of the subject as essentialist, naturalizing, and totalitarian. Thus, Derrida (1983; cf. Zirfas, 2010) deconstructs the idea of identity as selfsameness: given multiperspectivity and mutability, identity no longer aims at concordance. Instead, identity is constituted by difference to others; it is fragile, in a constant state of flux, unequivocal, and plurivalent. Adapting to 'The Age of the Internet,' Turkle (1995) replaces the modern identity question 'who am I?' by the postmodern question 'who am we?' and responds by noting, 'I am many.' The Internet is like a vast social laboratory. People experiment with ego constructions and reconstructions and leave with patchwork identities fitting in with postmodern life conditions.

Mostly, these authors applaud renouncing the unity of the person. Replacing unity and sameness with difference and heterogeneity, discontinuity and flexibility, and plurality and fragmentation is praised as liberation from obsessive identity constraints one-sidedly fixed to rationality and reason.

Objections have been raised. (1) Resemblances to schizophrenia or multiple personality disorders have been noted (Straub, 2000). (2) In fact, findings from dissonance theory and attribution theory, studies on dogmatism and split personality, clearly evidence that at least some consistency is indispensable for psychological well-being and mental health. (3) The fitting of a multiple decentered self-system with neoliberal demands for flexibility is criticized (cf. Münte-Goussar, 2010: 287f) and (4) Turkle's net user is denounced as "digital reincarnation of the modern Cogito-subject … freed from all bodily and sensual contaminations" (ibidem: 292f).

In response, mediating concepts have been introduced: a 'transversal subjectivity' is postulated, pervading subjects' differentiated parts and preventing the decomposition of plurality into 'multiphrenia' (Welsch, 1996: 847; cf. Klika, 2010). A 'linking competence' is devised, affording individuals a sufficient degree of coherence (Keupp, 1999: 271).

Modern Theories

These approaches assume the indispensability of a sense of psychic unity: subjects can only act if fleeting and contradictory ideas, inner multiplicity and heterogeneity, are somehow organized and structured. Yet, theories differ in their assumptions about how this is to be accomplished. These concern the grounding of identity – in material contents, in formal competences, or in both; the mechanisms stabilizing identity across time – consistent narratives and commitment to values; and, most importantly, the stance subjects are assumed to take toward themselves, whether a theoretical-observing or a practical one.

Material Content or Formal Competence

Traditional approaches deal with the establishment of identity and make content the basis for individuals' sense of unity and continuity: identity is socially determined by positions held and is experienced as unquestionable inasmuch as individuals have developed "need dispositions toward the fulfillment of role expectations" (Parsons, 1964: 32). This role identity is prevalent in societies in which positions are ascribed and social expectations internalized from early on.

For Erikson, ego-identity encompasses content and competences. Content consists in lifelong substantive commitments (e.g., to a partner, occupation, or worldview) incurred at the successful resolution of the adolescence crisis. Formal competences are then required for maintaining identity. The core is "accumulated trust that the unity and continuity one enjoys in the eyes of others corresponds to a competence to uphold inner unity and continuity" (1973: 107). Nowadays, however, people keep experiencing ever new crises (e.g., midlife crises and retirement crises) in which former commitments are revoked (e.g., by divorce, religious or ideological conversions, or loss of employment). Giddens takes this into account. He no longer speaks of commitments entered once and for all but of a multiplicity of choices: "Each of the small decisions a person makes every day – what to wear, what to eat, how to conduct himself at work, whom to meet with later in the evening … all such choices (as well as the larger and more consequential ones) are decisions not only about how to act but who to be … Lifestyle concerns the very core of self-identity in making and remaking" (1991: 81). Nevertheless, a formal competence – narrative competence – is required as well (discussed below). The model 'identity qua autonomous commitment' (Nunner-Winkler, 2002), too, integrates content and competence. Commitment needs an object (i.e., content is required). And

autonomous commitments presuppose competences (e.g., self-distancing and reasoning powers).

Krappmann defines identity exclusively on formal terms, debunking any substantive commitments as signs of rigidity, alienation, and reification. Identity is created in situated processes of balancing divergent expectations of different interaction partners and one's own strivings for "uniqueness and irreplaceability" (1969: 48). This involves "the efforts of an artist constantly juggling and balancing" (p. 56) and presupposes formal ego resources such as tolerance of ambiguity, role distance, and empathy.

Mechanisms for Stabilizing Identity

How do individuals uphold an inner sense of consistency and continuity despite changes? Some theories rely upon narrative competence: self-narrations "transform experienced contingency into something meaningful and significant … (integrating) different, even heterogeneous material into one coherent gestalt" (Straub, 2000: 132). Giddens, too, assumes that individuals who keep altering their lifestyle decisions, and thus their identity, need narrative competence to maintain coherence. "Self-identity becomes a reflexively organized endeavor … which consists in the sustaining of coherent, yet continuously revised, biographical narratives" (1991: 5).

Narrative competence, however, does not provide a convincing solution. People may unwittingly distort or repress unwelcome facts or experiences or construe rationalizations. This has implications for identity: upholding defenses consumes strength, and it may amplify distortions and entail unsuitable decisions.

Shoemaker notes the attractiveness of the concept of narrative identity given its good fit with the practical issue of moral accountability. Yet – so his philosophical objection – it does not answer the reidentification question – the proper question to ask for clarifying numerical identity. Instead, it answers the characterization question 'Who am I really?' Indeed, narrative identity presupposes numerical identity: "one can't be a person, on the narrative view, unless one gathers up the various experiences one has as a subject of experiences into a coherent narrative, but then the identity of that subject of experiences must be preserved across time for its experiences to be so gathered up" (2012: 12).

Another mechanism for stabilizing identity across time lies in autonomous commitment. This device, however, depends on a different description of the self-relation underlying the identity question.

Theoretical-Observing versus Practical Stance

Identity can be judged from two attitudes. In classical philosophy, identity is seen to arise "from comparing the content of consciousness with itself at different times and places" (Eisler, 1904: 482). Tugendhat criticizes this subject–object model and its epistemological presupposition that "all direct empirical knowledge must be based on perception … even knowledge about oneself" (1979: 34). Referring to Heidegger, he argues for conceptualizing agents' relationship to themselves as a practical one: "In saying 'I am' I do not in an 'aesthetically' observing mode refer to my being, I do not state my existence as a given, rather I take a stance in the mode of self-caring … I behave towards my being as to one I have to be" (p. 36). This is not "a theoretical comment on beliefs but a volitional practical stance" which implies "saying 'yes' or 'no' to being this or that way or to acting this or that way" (p. 37). It requires the ability to distance oneself from and reflect upon one's spontaneous desires. Tugendhat's analysis agrees with Frankfurt's conception of 'person': "A person is … prepared to … organize the preferences and priorities by which his choices are ordered … to consider whether what attracts him is actually important to him" (1988: 23). Thus, commitments to specific 'ideals' is a necessary constituent of personhood: if someone had nothing he cares so much about that he cannot bring himself to betray it, he is not a person but an object at mercy of his inner drives, fleeting whims, external constraints, or contingent circumstances (Frankfurt, 1993). Koorsgaard (1989), too, advocates a practical stance: we need to see ourselves as practical agents. This requires conceiving of oneself as a unified person at any time and across time, given we have only one body with which to act.

Postulating autonomous commitment as a core mechanism for achieving and stabilizing a sense of identity relies on the practical stance model. In the following, I will present some empirical evidence supporting this conception.

Sense of Identity – Some Empirical Findings

In philosophical debates, thought experiments are often used to clarify the structure of concepts. Such reflections draw their persuasiveness from the assumption that there is general agreement – about the best description of the thought experiments and about the intuitions guiding the responses (Garrett, 1998: 13ff). Thus, theoretical conclusions are based on what variously is described as "our considered judgments" (ibidem 1989: 50), "our core intuitions" (p. 51), "general agreement" (p. 52), "our core set of common-sense judgments" (p. 56), and "(the answer) most of us would give" (p. 91). Social sciences can test such assumptions. This is one of the many ways in which empirical research and philosophical reflection interact.

Findings about three topics will be reported: everyday understanding of the sameness of persons, constitutive facets of a sense of identity, and the stability of value commitments across a lifetime.

Everyday Understanding of the Sameness of Persons

Representative samples (of adolescents, university students, and elderly people) were presented in the following hypothetical scenarios in which a person experienced change (Nunner-Winkler, 2002):

1. Alzheimer's: by a grave disease (e.g., Alzheimer's), a man is reduced to the state of an infant (Nozick, 1981).
2. Brainwashing: a convinced democrat by brainwashing turns into a communist (ibidem).
3. 68 adherent: A formerly convinced adherent of the 1968 movement often protested against war and force of arms. Today he argues for military interventions in conflict areas.
4. Autobiographical memory: by an accident, a man suffers loss of his autobiographical memory. His powers of reasoning are intact.

In scenarios 1–4, the question was: 'Does … remain the same person? Why?/Why not?'

5. Nuclear power plant: Y from firm conviction got involved in Greenpeace. At the same time, he holds a leading position in a nuclear power plant. Does Y have identity problems? Why or why not?

The identity relevance of reasoning power (scenario 1) and autobiographical memory (scenario 4) was controversial (with about one-third in each case affirming or denying the identity or remaining undecided). The other items drew high agreement. Subjects ascribed most problems to persons who experienced a radical change in beliefs due to external manipulation (brainwash) or who acted against their beliefs (nuclear power plant). Few problems were expected in case of a 'normal' change in attitudes (68 adherent).

Thus, in general, beliefs are ascribed high identity relevance – an interpretation that is confirmed by justifications provided (e.g., "Principles are part of one's personality – someone turning around 180° is not the same man as before"). This is true, however, only of subjects who deem the specific beliefs important – either from their own perspective or from the assumed perspective of the protagonist (e.g., brainwash – different person: "Political beliefs are an important part of one's personality" and "Given he cares much about politics, these convictions are a significant aspect of his personality") – or believe they were betrayed (e.g., nuclear power plant – "Yes, he has big identity problems – after all, his beliefs are contradictory"). Subjects expect no identity problems, if they either do not care much about politics (e.g., brain wash – same person: "He only changed political attitudes") or believe that basic convictions have not really been betrayed (e.g., nuclear power plant – same person: "Maybe he accepts the NPW but fights against marine pollution or CO_2 emission").

Most subjects in referring to beliefs explicitly commented on the way the change came off. Manipulation (brainwashing) is seen to destroy identity (e.g., "Only if he changed on his own will, will he be the same person"). However, no problem arises if changes are seen to result from learning processes. These can be implicit: attitude change is viewed as a normal part of individual development (e.g., in the case of the 68 adherent, one could opine, "He has matured" or "Beliefs can change – children believe in Santa Claus"). Or they can result from explicit learning processes, i.e., by choice and with good reasons (e.g., "Beliefs have genuinely changed – of his own free will" or "He changed by rational thinking").

Facets of a Sense of Identity

Subjects were also given the following question: 'Imagine you would have different parents/different ideas about right and wrong/different looks/a lot more money/different interests resp. a different field of study resp. a different occupation/different friends/you were born and raised in a different country/belonged to the other sex. How different a person would you be?'

Across generations very few subjects gave high importance to 'money' and 'looks', whereas 'ideas about right and wrong' figured among the three most highly rated items (e.g., "If I had different principles, I'd be a different person"). The other two important items were parents and sex membership. As justifications indicate, these mostly stand for values, too (e.g., "Ideals are taken on from parents" and "Gender roles inform attitudes").

Despite these overall agreements, there are also clear interindividual differences. Some subjects accord high importance to 'looks' (e.g., "I define myself by my appearance"), but most don't (e.g., "Even if I had different looks, I'd still be the same person"). Some care a lot about their field of study (e.g., "If I got the place in psychology, I'd have a goal"), whereas others don't (e.g., "I don't define myself by university or by work. That's merely necessary for making a living"). Some see sex membership as important (e.g., "I am very feminine. I would not want to miss these weapons"), but others don't (e.g., "Different sex would not change me much; my basic attitudes toward life would remain the same").

Stability of Value Commitments across a Lifetime

A representative sample of young, middle-aged, and elderly adults were asked to evaluate 25 possibly morally relevant scenarios (e.g., homosexuality, working mother, and leaving the church) (Nunner-Winkler, 2005). Large differences were found between the generations. This change in moral understanding can be attributed to a change in the grounding of morality. Traditionally, moral norms were derived from authorities – God, the church, and nature. Today, they are justified in terms of a hypothetical consensus of all concerned. This change has led to a minimal morality that forbids harming others directly (e.g., do not kill, lie, steal, etc.) or indirectly (e.g., do your duty) and attributes all other behavior to the personal realm. To illustrate, most of the older subjects condemned homosexuality (e.g., by stating that 'it is sinful', 'unnatural', 'pathological', 'sickening'), whereas most of the youngest accepted it ('whom love befalls' and 'that's their decision'). Interestingly, most older subjects – though well aware that the zeitgeist has changed (e.g., 'younger people are more liberal') – held on to attitudes that they acquired in adolescence.

Implications for Sense of Identity Theories

The disagreement found in border cases (Alzheimer's and loss of autobiographical memory) matches philosophical disputes about the relative importance of physical or psychological criteria. In normal cases, however, everyday judgments rely on psychological criteria backing the concept of identity qua autonomous commitment: most subjects saw their convictions as decisive in defining their personhood. Most of the older subjects held on to their former beliefs – maybe as a way of stabilizing identity in times of rapid changes. Alterations of beliefs, however, are not excluded. Individuals changing their mind of their own free will and with good reasons (i.e., by learning processes) do not jeopardize their identity.

This model disagrees with other approaches. (1) Gidden's claim that all lifestyle choices are relevant to identity does not hold up. Individuals decide which choices they deem important – and they differ in these decisions. (2) Krappmann's rejection of content as alienating is not shared – subjects understand their value commitments as constitutive of their personhood. (3) Narrative competence may not be so relevant. The (assumed)

truth of essential beliefs counts more than the way they are acquired. To illustrate: being sure that Jesus is God's son presumably means more to Paul than the story of his conversion at Damascus. (4) The value commitment model questions the common assumption that identity requires difference: if I identify with specific values, I want them not to be distinctive of me but to be shared and propagated by others, too. The emphasis on difference seems to reflect a confusion of identity and uniqueness. Thus, people strive toward unique interests, original hobbies, and special lifestyles to secure their irreplaceability. Frustrated, they then experience that all newly invented identity markers are socially absorbed and commercially coopted (Cohen and Taylor, 1976). However, sense of uniqueness does not result from public displays of singular features, but from authentic and genuine commitment (Keniston, 1968; Nunner-Winkler, 1985): it is a necessary by-product, and it will inevitably be missed if directly accessed (Elster, 1987).

Conclusion

The identity questions – what constitutes and stabilizes personal identity? And how do people attain a sense of identity? – have found different answers. Numerical identity in substance-based theories rests upon some essence that remains constant (soul, body, and brain), in relational theories on psychological connectedness (memories, beliefs, and desires). The relative weight of physical versus psychological criteria is disputed. This theoretical dissent corresponds to disagreements in everyday understanding (e.g., about how to deal with loss of reasoning power) and in common practices (e.g., medically supporting PVSs yet honoring advanced directives).

Sense of personal identity is addressed by theories taking a first-person perspective. Postmodernists claim that personal unity is neither existent nor necessary. Instead, they rejoice the emancipation from identity constraints. In contrast, classical theories assume that individuals need some consistency and continuity, yet differ in how they see this requirement fulfilled. Empirical research supports the assumption that individuals attain a sense of identity by committing themselves to values that they hold despite outer changes but revise in the light of new insights.

The two discourses are interrelated: the criteria used in philosophical reflections for defining identity must have some counterpart in everyday understanding. And social science analyses of components of a sense of identity are relevant for the constitutional debate inasmuch as they accommodate the fact that persons – in contrast to things – have a first-person perspective.

Abstract

Personal intelligence concerns the ability to reason about personality and personality-related information; it includes both self-knowledge and knowledge about the personalities of other people. Personal intelligence encompasses a wide range of areas of reasoning from perceiving cues to personality to planning one's life. There are individual differences in such reasoning, and some people are much better at such reasoning than others. The article examines the nature of intelligences, personality, and personal intelligence. The skills involved are examined as well as how they are measured and the relation of the intelligence to life criteria.

We vary as to how well we understand personalities – or, at least, how well we *think* we do. Some of us claim great skill in this area; others less so. Oprah Winfrey claims great empathic ability – and she argued that her success as a daytime television host was because she relied on her skill in drawing out others:

> I think the show's been successful because … I relate to the core of everyone's pain and promise because I've known pain and promise … Having that understanding and that connection has really given me wings to fly…
>
> Kantrowitz et al., 24 October 2005: p. 48

The best-selling author Tucker Max – the author of the rowdy, *I Hope They Serve Beer in Hell*, by contrast, has represented himself as 'not very adept at picking up subtle social cues' – although whether this is part of a satirical façade or an honest self-appraisal is difficult to discern (Max, 2009: p. 58).

The idea that there exist skills to understand personality and that people vary in those skills is an ancient one. In 2500 BCE, the Egyptian sage Ptahhotep instructed leaders to interview those around them in private to gauge their character, and by 200 BCE, Theophrastus had outlined a score of personalities to watch for, from the miserly person to the talkative one (Ptahhotep, 2003/*c*.2450 BCE; Theophrastus, 1970/*c*.319 BCE).

Personal intelligence, the topic of this article, concerns the ability to reason about personalities – both one's own and the personalities of other people. According to a theory of personal intelligence, there are important forms of reasoning about personality that can be described, and some people are much better at such reasoning than others (Mayer, 2008). In this article, we examine the nature of intelligences and of personality, personal intelligence as a theory, the skills involved and how they are measured, and the relation of the intelligence to life criteria.

A Contemporary View of Intelligences

Personal intelligence is concerned with thinking clearly and accurately both about one's own personality and the personalities of others. To understand personal intelligence, it helps to begin with an understanding both of contemporary intelligences and of personality itself.

Intelligence Theories Today

Perhaps the most influential theories of today view intelligence as a three-tiered hierarchy of mental abilities from the most general at the top to highly specific mental abilities at the bottom – sometimes referred to as the three-strata or Cattell–Horn–Carroll model (e.g., Carroll, 1993; McGrew, 2009). At the top of the hierarchy is *g* or general intelligence. Charles Spearman first proposed *g* as a general capacity to reason abstractly: to see similarities and differences, to follow the logic of an argument, and to draw correct conclusions from information (Spearman, 1904). And, as its name implies, *g* is general – a set of capacities that are applicable to many diverse domains of human problem-solving (Spearman, 1904; Sternberg and Grigorenko, 2002). Commensurate with its uppermost position in the three-stratum hierarchy, *g*'s position distinguishes it from the broad areas of problem-solving people carry out at the second level immediately beneath it. These still-broad areas of problem-solving – 'broad intelligences' – are estimated at between 8 and 14 in number. They include fluid reasoning (the ability to deduce principles from information), verbal intelligence, visual-spatial thinking (the ability to store and recall visual representations), long-term memory and retrieval, auditory processing (including the ability to discriminate speech sounds), processing speed, performance (mechanical) intelligence, and working memory capacity (Carroll, 1993).

At the bottom of the hierarchy are the nitty-gritty specific abilities on which our cognition rests: in the verbal–comprehension area, these include decoding words, spelling ability, writing speed, and reading comprehension, among others. As a second example, in the 'long-term storage and retrieval' area of broad intelligence, the skills include associative memory, associational fluency, and free-recall memory. Seventy-three such specific skills have been identified according to an estimate, and perhaps there are upwards of 100 (Carroll, 1993; McGrew, 2009).

The 'Felt' or 'Hot' Intelligences

A group of intelligences that are not yet included in the three-stratum models are the 'hot' or 'felt' intelligences – personal, emotional, and social intelligence – so-called because when we use them we are thinking about information that especially

matters to us and is deeply relevant to our relationships with others. Robert Abelson first suggested that people engage in 'hot cognition' when their attention shifts from traditional problem-solving involving language, objects, and spaces to matters that are of particular personal concern to them (Abelson, 1963). In the 1980s, researchers uncovered a host of effects of such personal information on thought, creating a new field called 'cognition and affect' along the way (Abelson, 1963; Blanchette and Richards, 2010; Bower, 1981; Isen et al., 1978).

For example, people who are in good moods often see positive events as more likely and positive instances as better examples of categories than those in negative moods (Blanchette and Richards, 2010). Additionally, psychobiologists have detailed how memory about the self, for example, involves different brain regions than memory more generally, and information that challenges one's self-knowledge is processed differently from other information (Klein et al., 2004; Vaillant, 2000). The idea that some broad intelligences might focus on such personally relevant hot or 'felt' intelligences was a natural development of this line of thinking (Mayer, 2014; Salovey and Mayer, 1990). That said, some psychologists continue to debate whether hot intelligences exist and can be measured (e.g., Locke, 2005; Maul, 2011; Zeidner et al., 2001). And because measures of these felt intelligences have been developed only recently, they have yet to be integrated into the hierarchical model of intelligence.

Personality and Personal Intelligence

Among those felt intelligences, personal intelligence is unique in its focus on personality itself. Just as verbal intelligence concerns a focus on language and spatial intelligence concerns three-dimensional objects in space, personal intelligence involves an understanding of how personality operates.

According to one contemporary view, personality is closely connected to four surrounding systems: First is our body (and especially our brain), from which personality emerges; personality must meet the needs of those biological systems. Second, personality navigates the setting in which we find ourselves – on a train, at work, walking down the street, or in a sports arena. These settings provide a foundation, in turn, for the psychological situations (third) that emerge from them. These situations include such meaningful sets of actions as getting up in the morning, going to work, asking a colleague for help, or painting ourselves blue and screaming at the top of our lungs in a basketball arena. And fourth, there are groups to which personality belongs – political parties, religious or secular groups, artistic movements from which we draw, in part, our identity (Mayer, 2005; Mayer and Korogodsky, 2011).

These four surrounding systems tell us what personality must do: our personalities negotiate our personal needs – those wants and desires that are directed in part by our body, brain, and psychological systems. To meet our needs, we act in the outer environment: our settings, situations, and groups – through negotiation, reciprocation, love, and sometimes through conflict or self-deprivation (Buss, 2008; McAdams and Pals, 2006).

To negotiate these relationships and attain benefits from them, each of us has at our disposal our major psychological subsystems – our motives, emotions, intelligences, and models of ourselves and other people. According to contemporary psychologists, personality, in essence, is the system that organizes the rest of an individual's psychological systems – those same motives, emotions, capacities for self-management, and other areas of functioning (Mayer, 2007). Although personal intelligence begins with an intuitive understanding of who we and other people are, it may proceed to a more formal understanding that may approximate to some degree what psychologists have learned about personality. Personal intelligence is personality's guidance system – the part of personality that helps us to motivate ourselves, understand our social and emotional traits and the traits of others, and to choose our goals and understand other people's goals (Mayer, 2014).

Personal Intelligence: Theoretical Bases, Precursors, and Related Concepts

Theoretical Bases and Precursors

Theoretical Bases

The contemporary approach to personal intelligence is an outgrowth of many previous ideas. One theme that wends its way through earlier works is that throughout human evolutionary history, the ability to reason about one's own and others' personalities conferred an adaptive advantage. According to Dunbar (2009), for example, evolution selected for larger human brains so that our evolutionary ancestors could keep track of the behaviors of those in their group – through observing them directly, but also through gossiping about them. For example, Haselton and Funder have observed that judging others' personalities has the characteristic of an instinct in that the phenomenon happens automatically, quickly, and universally (Haselton and Funder, 2006).

Converging evidence for this innate interest in personality comes from our earliest written documents – in which can be found a concern with the issues of personality from around the world (Mayer et al., 2011). Already during the Great Transformation – the period from 800 BCE to 200 BCE – written records frequently addressed the best way to live, and how to guide one's personality and to understand the personalities of others. In ancient China, Confucius spoke of the different personalities of his students and how they required different handling. In the Middle East, Kohelet (Ecclesiastes) concerned himself with how best to live a life. In ancient Greece, Plato extolled the virtues of self-knowledge, and Aristotle's successor in the Greek Lyceum, Theophrastus, enumerated over a dozen character types mostly recognizable still today, including the talkative type, the stingy type, and even distinguishing the city slicker from the country bumpkin (Theophrastus, 1970/*c*.319 BCE). Writers took up the continued description of personalities in their works, and engaged in 'characterology,' developing highly nuanced literary depictions of different types of people (Roback, 1927). Physicians sought to understand differences in personality and how a person's physical health might bring those about (Ellenberger, 1956).

Precursors

More recent precursors of personal intelligence emerged during the past century of psychological research. For example, in 1947, Wedeck sought to discover whether there was an 'ability

to understand psychology,' that was independent of Spearman's *g*; Wedeck's results were somewhat disappointing as the findings provided weak evidence at best for such a new area of reasoning (Wedeck, 1947). A few years later, at the Menninger Clinic in Kansas, a group of psychologists began studying 'psychological mindedness.' Their conception was that certain patients had an ability to 'think psychologically' about themselves and others (Appelbaum, 1973). Psychological mindedness, as those mental health practitioners saw it, involved "A person's ability to see relationships among thoughts, feelings, and actions with the goal of learning the meanings and causes of his experiences and behaviour" (Appelbaum, 1973: p. 36). And, it included:

> …the easily observed talent that some people have, and others lack, to 'see', 'know', 'feel' covert and inexplicit psychological events … [with] … the goal of learning the meanings and causes of … behaviour…
>
> Appelbaum, 1973: p. 36

Gardner (1983) drew on such earlier ideas when he suggested there might be two personal intelligences, as part of his vision of multiple intelligences (MIs). The first of these was 'intrapersonal' and the second, 'interpersonal.' The core of intrapersonal intelligence involved deciphering inner-feeling states – overlapping in part what, today, is called emotional intelligence – and this intrapersonal intelligence, as Gardner viewed it, also concerned a sense of identity (Erikson, 1950). For Gardner, people also drew on the second, 'interpersonal' intelligence, to understand other people, their personalities, the rules of society, and adherence to social customs (Gardner, 1983). Yet, Gardner actively discouraged anyone interested in his theories from developing intelligence tests based on them (Gardner, 1999: p. 80). He may have succeeded in part in dampening such empirical investigations: as one researcher recently opined, "Despite the popularity of the MI idea in some educational circles, there is virtually no evidence for the theory" (Hunt, 2010: p. 119).

Alongside psychological mindedness, and the intra- and interpersonal intelligences, some researchers examined specific abilities that were (and are) highly relevant to a possible personal intelligence. Funder (2001) speculated on the characteristics of a 'good judge' – an individual who is particularly accurate at evaluating a target-individual's personality, and he outlined characteristics of a good judge, including extraversion and general intelligence. Pillemer (1998) concluded in his book on personal memories that there might exist people with an 'autobiographical intelligence' who employed recollections from their past to motivate and guide themselves.

Drawing on sources that included ability conceptions of emotional intelligence, Funder's concept of the good judge, and studies by Jackson (1972) of inferential accuracy, Christiansen and colleagues proposed a theory of a 'dispositional intelligence' that drew on "Three declarative knowledge structures …: (a) knowledge of trait-behavior linkages, (b) understanding of situation-trait relevance, and (c) proficiency at trait concepts" (Christiansen et al., 2005: p. 126); and the authors developed a scale we will review in our section on measurement.

A Theory of Personal Intelligence

A pair of theoretical articles in 2007 and 2008 drew together many of these earlier works and described a new theory of personal intelligence. The theory divided personal intelligence into four areas of problem-solving: (1) identifying cues to personality, (2) forming models of oneself and of other people, (3) guiding choices using personally relevant information, and (4) systematizing one's goals and life plans. These areas are shown in **Figure 1** (Mayer, 2008, 2009). Before the theory, the term 'personal intelligence' had been used in a number of ways, from the title of a gossip column to a shorthand way to remark upon Gardner's intrapersonal intelligence (see, for example, Park and Park, 1997).

The characteristic attributes of people high in these mental abilities were outlined in a second article developing the theory. For example, those who are especially good at 'identifying cues to personality' might often express an unstable sense of self as new information was drawn inward; they also were better at seeking feedback, often through asking nonbiasing questions about themselves, such as 'how can I improve at this job,' as opposed to the more biasing, 'am I doing a good job?' Individuals who were especially good at guiding their own choices were expected to better fit their personalities with their occupations, and those who could systematize their own plans would exhibit "goals that are well chosen and mostly consistent with each other" (Mayer, 2009: Table 2, p. 52). With the theory itself laid out, we turn next to empirical work in the area.

Measuring Personal Intelligence and Related Competencies

Intelligence, Competencies, and Ability Measurement

The optimal approach to measuring an intelligence or a competency is to employ an ability approach – that is, test-takers are given problems to solve in the area and their answers are compared against a standard of correctness. Because people are generally unable to give accurate self-reports in the area, there is little point to asking people how smart or competent they are. There are many reasons for this, including that many people lack the understanding necessary to evaluate their own performance (Dunning, 2005).

The terms 'intelligence' and 'competency' both refer to people's capacity to successfully carry out certain tasks, but the two concepts differ somewhat in their emphasis. Intelligence refers centrally to a general ability to think – a person's ability to function well in defined, broad area of problem-solving (Carroll, 1993). Competencies, on the other hand, refer to attained, demonstrable levels of performance in a specific area, often as judged against a socially defined criterion. In the case of personal intelligence, aptitude would be assessed by asking test-takers to solve a number of general problems believed to reflect their ability in the domain, and comparing their answers to those of other people. By contrast, competencies are more often assessed in a specific context. For example, a human resources professional who selects candidates for various positions needs to be competent to do so – meeting or exceeding the organization's standards for correctly placing individuals in their jobs. That specific performance in a given

Figure 1 An overview of personal intelligence. Personal intelligence can be thought of as drawing on four broad areas of problem-solving depicted in the figure. By carrying out reasoning across the areas, people are better able to understand and anticipate their own and other people's actions. Illustration adapted from Personal Intelligence by John Mayer. Copyright © 2014 by John Mayer. Used by permission of Farrar, Straus and Giroux, LLC.

context is a competency. Most attention to personal intelligence so far has been on measuring the intellectual ability.

Two Classes of Ability Scales

Ability scales or tests of personal intelligence can be divided into two classes: those that focus on a specific ability or context, and those that measure the overall intelligence. Many of the first specific measures were not designed with personal intelligence in mind, but plainly tap one or another part of the concept. Existing specific measures fall into areas of being 'a good judge' in relation to evaluating other people's characteristics accurately, and of understanding traits. Another relevant group of measures, arguably, are ability measures of emotional intelligence, because understanding emotions are part of understanding personality. Ability measures of emotional intelligence are not reviewed here as the Encyclopedia contains a separate article on emotional intelligence.

Specific Area Scales

This section examines several measures of specific areas of personal intelligence.

- The Good Judge: The key set of studies of being a good judge involve, not an ability scale, but rather a laboratory index of performance that examines how well participants assess the personalities of other people in their groups. For example, Letzring (2008) examined the best judges among participants in the Riverside Accuracy Study, conducted at the University of California, Riverside. Letzring indexed accuracy according to how well a judge's perception of a person matched several criteria including the participant's self-description, other participants' impressions of the target person, and clinical interviewers' impressions. The best judges were high in social skills, agreeableness, and positive adjustment – as independently rated by undergraduate coders from videotapes of the judges' interactions in small groups.
- Measurement Scales of Good Judges: Moving to actual measurement scales, Vogt and Colvin (2005) collected ratings of the personalities of 143 undergraduates from their parents, observers, and behavioral ratings by judges who viewed them on videotape. They developed indices of how closely participants evaluated themselves relative to each of those observers and demonstrated moderate correlations among the different indices. Overall accurate self-knowledge (i.e., smaller discrepancies) correlated with well-being.
- Trait Understanding: Christiansen et al. (2005) developed a measure of 'dispositional intelligence,' a test-taker's knowledge of traits including how traits relate to behaviors and to situations. For example, the following item from their test asks about trait–behavior relationships:

> Lucy's coworkers all describe her as efficient, thorough, and persistent.
> Most likely Lucy also
> A. feels the need to be around a lot of people
> B. has a great deal of sympathy for those less fortunate
> C. does not often give in to her impulses
> D. enjoys fantasizing and daydreaming (Christiansen et al., 2005: p. 131).

The researchers identified "C. does not often give in…" as the correct answer because self-control is related to the overall trait of conscientiousness, about which the item inquires. As a second example from their test, an item that related traits and situations asked:

Which of the following situations are most relevant to the trait of sociability?

A. A week after taking a final exam, you go to the professor's office to find out your final grade and you run into a classmate there. While you both are waiting for your grades, your classmate tells you he found the course difficult and is concerned about his performance.
B. You have just heard that your supervisor received a promotion that he/she has wanted for a long time.
C. Over the last 2 years, you have been employed at a job that entails working by yourself. Your boss offers you a chance to do essentially the same thing, but in a group of coworkers (Christiansen et al., 2005: p. 148).

Here, the authors identified "C. Over … in a group of coworkers" as the correct answer, because the new job directly impacts the ability to fulfill one's need for sociability. In Christiansen et al.'s research, an expert panel of judges (two graduate students and three doctoral-level psychologists) chose the correct answers to each of the 45 questions and exhibited high levels of agreement in doing so. The authors reported that the finished scale of 45 items exhibited a reliability of $r = 0.82$ for the main sample of 157 participants in their larger study. Test-takers who scored high were able to better predict, relative to low-scorers, the personality attributes of an interview candidate who had been videotaped.

General Scales of Personal Intelligence

The Test of Personal Intelligence (TOPI) was designed as a general scale of personal intelligence that measures a broad range of problem-solving abilities in the area. The TOPI asks questions that tap the labeling of inner states such as fatigue and dreams, and understanding one's reputation; it asks about trait knowledge using items with formats similar to those on the dispositional intelligence scale, and it asks questions about planning and goal setting, among other areas. The most recent version of the scale, the TOPI 1.2, contains 16 different item clusters, each asking about a different problem-solving area of personal intelligence (Mayer et al., 2012).

Omnibus scales of personal intelligence such as the TOPI 1.2 serve as *de facto* experiments in whether the construct exists. If personal intelligence is indeed a broad intelligence, then performance on the wide range of problem-solving measured by the scale ought to be reasonably highly correlated and represented well as a single global factor with subsidiary areas. Mayer, Panter, and Caruso were able to model the scale in that fashion using confirmatory factor analysis (Mayer et al., 2012). Reliability for the 134 item TOPI 1.2 was reported at 0.89, although in a recent unpublished study its reliability was 0.83 (Mayer et al., 2012). A short form, the TOPI MINI-12 has reliability variously calculated between $r = 0.52$ and 0.82 depending upon the sample, and correlates reasonably well with the overall TOPI 1.2 (Mayer et al., 2013).

Competencies of Personal Intelligence

People who develop their personal intelligence employ a wide range of competencies to understand themselves and those around them, as reflected by the tasks of the specific and general measures of the abilities related to the intelligence. A full-length review of many of these specific skills is available elsewhere (Mayer, 2014). Here, it is worth pointing out that people may use their personal intelligence to develop competencies that are specifically related to their individual needs. For example, a high-school student hoping to understand his own and his friends' behaviors may seek to focus, for example, on skills at obtaining feedback, on eliciting information about people, and on integrating information into a balanced picture of himself and others (avoiding naive optimism or an overcritical attitude). A new employee training in a human resources department of an organization, on the other hand, may want to hone both her interviewing skills and ability to make predictions about an applicant's performance on the job. And, a psychotherapist will want to build on his skills of empathy and setting limits. The new university president who previously was uninterested in college athletics may realize that he should attend student rallies clamoring for the popular basketball coach to remain at the university rather than accepting a rival school's job offer. Although there are shared factors across these contexts – the person's overall personal intelligence – there are also unique motivational and training requirements in each case so as to reach a level of competency.

The Relation of Personal Intelligence to Assorted Criteria

Relation to Socioemotional Traits, Interests, and Other Self-Evaluations

Self-Estimated Personal Intelligence and Psychological Mindedness

A growing number of findings have related personal intelligence to a variety of criteria. For example, intelligences are generally uncorrelated with people's estimates of their own mental abilities, and personal intelligence is apparently no exception to the rule. Using an online sample, Moore (2012) reported a correlation consistent with past research – of just $r = 0.11$ – between a measure of self-estimated personal intelligence and the TOPI MINI-12 (Only a portion of the TOPI MINI and SEPI were used. See Moore, 2012). People with greater self-reported interpersonal competency on the Interpersonal Competency Scale (Buhrmester et al., 1988) likewise show no significant relationship with the TOPI 1.2 overall (Mayer et al., 2012). Personal intelligence is, however, related $r = 0.30$–0.40 to self-reported psychological mindedness (Mayer et al., 2012), where such psychological mindedness represents a personal interest in understanding personality coupled with a belief that such understanding is of importance (Conte et al., 1990).

Measures of Normal Personality Traits, Work Behavior, and Clinical Symptoms

Studies with the TOPI 1.2 and TOPI MINI indicate that personal intelligence has low positive correlations – roughly between $r = 0.10$ and 0.20 – with three of the big five personality traits: Openness, Conscientious, and Agreeableness (Mayer et al., 2013; Mayer et al., 2012). A study with the TOPI MINI-12 and the Counterproductive Work Behavior Checklist (Spector et al.,

2006) found that those lower in personal intelligence engaged in significantly more abusive relations ($r = -0.16$), sabotaging behaviors ($r = -23$), and thefts at work ($r = -0.15$), all $p < 0.05$ (two-tailed), using a sample of 336–379 anonymous online responders (Moore, 2012). And in a study using measures of psychiatric symptoms, people who scored lower on the full TOPI 1.2 also exhibited more symptoms of narcissism and dependent personality (Mayer et al., 2012).

Relationship to Mental Abilities

The TOPI 1.2 correlates with verbal intelligence at about the $r = 0.40$ level. Although the TOPI asks mostly about cues to personality, traits, motives, and goals, and has just a few items concerning emotion, the TOPI 1.2 correlated $r = 0.68$ with the strategic areas (understanding and managing emotions) of the Mayer–Salovey–Caruso Emotional Intelligence Test (MSCEIT). In the same study, the TOPI 1.2 also correlated $r = 0.53$ with the Reading the Mind in the Eyes Test – a measure of skill at inferring inner states from the eyes, inversely related to autism (Mayer et al., 2012).

People who score high on Christiansen et al.'s (2005) scale of dispositional intelligence are better able than low scorers at identifying how job applicants in a video described their personalities. Finally, people who draw accurate conclusions from reading paragraph-length descriptions of a person's behavior, as opposed to misreading the situation or drawing black-and-white or biased perceptions, also score higher on the TOPI MINI-12 (Allen and Mayer, in preparation).

Discussion and Conclusion

The a priori theoretical argument for personal intelligence is evolutionary and adaptive: people who developed skills at understanding their own and others' personalities had an adaptive advantage over others, and as a consequence, our evolutionary ancestors developed a capacity to reason in this domain.

Personal intelligence is, relatively speaking, a newly introduced intelligence. In the principal theory we discuss, it divides into a number of problem-solving areas from identifying personality-related information to systematizing life plans. Psychologists have developed measures of some of the specific abilities involved, such as knowledge of traits, and of the overall intelligence (Christiansen et al., 2005; Mayer et al., 2012). They also have developed scales that measure many different kinds of reasoning in the area. Factor analyses indicate that these specific areas of problem-solving form a unitary area of ability. Measures of personal intelligence are related to measures of verbal intelligence at a moderate range, and somewhat higher with 'hot' or 'felt' intelligences (depending upon one's preferred terminology), including the MSCEIT and the Reading the Mind in the Eyes Test (Baron-Cohen et al., 2001). Preliminary findings indicate that personal intelligence has promise for predicting important outcomes in people's lives. That said, much research remains to be done to further develop the theory, demonstrate that it exists independently of general and hot intelligences, and to improve the measures of this ability.

Personal Projects

Brian R Little, University of Cambridge, Cambridge, UK and Carleton University, Ottawa, ON, Canada

Abstract

Personal projects are extended sets of personally salient action in context. They range from the incidental tasks of typical Thursdays to the overarching commitments of a lifetime. Little (1983) provided a rationale and methodology for the study of personal projects with emphasis on their consequences for well-being and human flourishing. Personal projects analysis (PPA) is a multimodular, flexible assessment suite based on 12 explicit measurement criteria. PPA provides modules for assessing the content, appraisal, impact, dynamics, and social ecology of personal projects. Research broadly confirms the proposition that well-being comprises the sustainable pursuit of core projects in our lives.

Personal projects are constituent elements of daily lives. They can range from the seemingly inconsequential acts of Thursday mornings ('put out the dog,' 'trim my toenails') to the overarching commitments of our lives ('help my mother through Alzheimer's,' 'liberate my people'). Little (1983) introduced a rationale and methodology for the study of personal projects, in part as a contribution to the person–environment debate that was raging between personality and social psychology at the time (e.g., Mischel, 1968). The methodology, personal projects analysis (PPA), has been subsequently adopted in various fields of social and behavioral sciences, from psychology (e.g., personality, social, developmental, health, environmental, organizational) to occupational therapy, rehabilitation science, environmental planning, gerontology, management, and public policy (Little et al., 2007).

Little introduced personal projects as units of analysis that uniquely capture features of both individuals and the contexts in which they act. Personal projects can be formally defined as "extended sets of personally salient action in context" (Little, 2007, p. 25). Each term can be delineated as follows:

Extended: A project is not a momentary act, but typically a sequence that is extended in space and time (minutes, hours, days, or years).

Set: A project encompasses a series of actions that are considered interrelated by the project pursuer.

Personally salient: A project is a noteworthy aspect of the life of the person who pursues it, and can be defined as such only by that person.

Action: A project is not a passive response to external forces but an intentional sequence of behavior involving cognitive, affective, conative, and volitional processes.

In context: A project is enacted in physical, social, cultural, and temporal contexts that can facilitate or thwart project pursuit.

The Social Ecology of Personal Project Pursuit

From the outset, personal projects research explored the impact of project pursuit on well-being and the quality of lives (Little and Ryan, 1979; Palys and Little, 1983). It was a central theoretical element of a social ecological model of human development, depicted in **Figure 1** (Little, 1999). The model posits that well-being is influenced by stable and dynamic features of both persons and their contexts and that each of these sources of influence is integrated in the personal projects individuals pursue.

Note. The saturation of colors refers to the degree of fixedness of the element. Greater saturation (more intense color) indicates that the element is more resistant to change; lower saturation (less intense color) indicates that the element is more flexible. The colors blend together in the *Personal projects* box to symbolize that individual (purple) and contextual (turquoise) features merge through personal projects.

Figure 1 Social ecological model of well-being (Little, B.R., 1999. Personal projects and social ecology: themes and variations across the life span. In: Brandtstädter, J., Lerner, R.M. (Eds.), Action & Self-Development: Theory and Research through the Life Span. Sage Publications, Thousand Oaks, CA, pp. 197–221).

Personal projects share features with other personal action constructs (PAC units) that arose in the 1970s and 1980s (Little et al., 1992), and differ from traditional units of analysis in personality psychology such as traits or narratives. Among PAC units, personal projects occupy a middle-level position, with personal strivings and related goal units focusing mainly on the internal motivation behind actions, and life tasks being more externally oriented, focusing on age-related normative expectations. A detailed account of the development of personal project theory and how personal projects differ from other constructs such as personal goals appears in Little (2007).

PPA Methodology

PPA is a multimodular instrument designed to measure personal projects in research, clinical, and other applied settings. PPA is typically presented in written form. A computer-enhanced version has been developed (see the Excel spreadsheet in Appendix). PPA can also be administered through an oral interview (Little and Gee, 2007) and this is particularly valuable for use in applied settings.

Measurement Criteria

PPA complies with 12 measurement criteria that are regarded as a propaedeutic to more conventional psychometric criteria (Little, 2000b). These criteria are presented in **Table 1**.

These 12 criteria are implemented in PPA through four standard modules: Project Elicitation, Project Appraisal, Hierarchical Analysis, and Cross-Impact Matrices.

Project Elicitation

Individuals are presented with a description and examples of personal projects, and asked to list their personal projects in 10–15 min. As an illustration, **Figure 2** shows the spreadsheet form completed by Peter, a graduate student in psychology. This module generates information about the number and content of a person's projects and about the idiosyncratic language through which they are expressed. Typically participants list around 15 personal projects although this will vary as a function of such factors as age and openness (Lawton et al., 2002; Little and Gee, 2007; Little et al., 1992).

The listed projects can be analyzed by traditional content analytic procedures. The standard categorization framework shows high interrater reliability and comprises eight main categories based on domains of activity: interpersonal (e.g., phone my parents more often), academic or work (e.g., complete my PhD), intrapersonal (e.g., become a better person), recreational/leisure (e.g., have fun with my friends this week-end), health (e.g., lose 15 pounds), maintenance (e.g., organize my time to work less during week-ends), and others. The most frequent categories are interpersonal and academic or work projects (depending on whether the participants are students or in the work force). Participants themselves can also be asked to classify their projects into these categories and this allows for greater precision (e.g., "work on Suzanne's car" might be primarily a work project or an interpersonal one). Project categories are related to well-being outcomes.

Table 1 Methodological criteria underlying personal projects analysis

Criteria	*Description: PPA…*
Reflexive	Provides a theoretical framework that is jointly applicable to the scientist's actions and those of the participants being studied.
Personally salient	Focuses on noteworthy aspects of the participants' existence, as defined by themselves and expressed in their idiosyncratic language.
Evocative	Gives participants an opportunity for self-reflection and new insights about themselves.
Ecologically representative	Documents the influence of objective and subjective features (e.g., physical, social) of the participants' ecosystem.
Temporally sensitive	Documents the dynamic nature of personal projects through their stages of progression.
Social indicator potential	Provides policy-relevant data on the quality of the social ecological settings where the participants evolve.
Systemic	Documents the interrelations between the multiple projects pursued concomitantly by participants, and which, aggregated, comprise their personal project systems.
Middle-level	Provides access to both lower order (e.g., acts) and higher order (e.g., values and aspirations) aspects of human experience.
Modular	Provides modules that can be selected, adapted, and supplemented to offer the best answer to the study question, in the specific research setting.
Conjointly idiographic and normative	Allows analysis of relationships between projects dimensions at the participant level (across each participant's different projects) and at the sample level (across all the participants' project systems).
Integrative	Provides a single instrument to document cognitive, behavioral, affective, and social aspects of the participants' experience, integrated around their personal projects.
Directly applicable	Focuses on a tractable unit of analysis that can be targeted in individual and social interventions to promote well-being.

Note. Content adapted from Little, B.R., 2000b. Persons, contexts, and personal projects: assumptive themes of a methodological transactionalism. In: Wapner, S., Demick, J., Yamamoto, T., Minami, H. (Eds.), Theoretical Perspectives in Environment-Behavior Research: Underlying Assumptions, Research Problems, and Methodologies. Kluwer Academic Publishers, Dordrecht, Netherlands, pp. 79–88.

For example, in a sample of seniors (Lawton et al., 2002), recreational/leisure projects were positively associated with positive affect, and interpersonal projects were associated positively with positive affect and negatively with depression. Salmela-Aro (1992) has shown that students seeking psychological counseling frequently report intrapersonal projects, which she found negatively associated with sense of coherence, self-esteem, mental health, and life satisfaction. Given the preponderance of intrapersonal projects (4 out of 15) in Peter's list, we might expect him to experience limited levels of well-being. However, this might be compensated by the positive affect that he derives from his three interpersonal projects and his two recreational/leisure projects.

Project elicitation

To start, please take 10–15 minutes and type in the following cells as many personal projects and activities you can that you are currently engaged in or considering – remember these need not be formal projects or even important ones – we would prefer you to give us more of the everyday kinds of activities or concerns that characterize your life at present.

Please be completely honest in your answers, as they will not be connected to your name. Also, if possible, please fill out this survey in one sitting.

Project #	Project description
1	Become a better person
2	Complete my PhD
3	Exercise 4 times a week
4	Move in with Emily
5	Be less anxious
6	Lose 15 pounds
7	Have fun with my friends this week-end
8	Go at the beach for a couple of days
9	Organize my time to work less during week-ends
10	Walk the Way of St.James
11	Phone my parents more often
12	Be happy
13	Write the first part of my dissertation
14	Write that research report that has been due for one month
15	Adopt a child

Figure 2 Project elicitation module.

Linguistic aspects of project content have also been analyzed. For example, Chambers (2007) presents a convincing argument that the language we use to communicate about our projects is strongly related to their likelihood of successful pursuit. Phrasing projects as 'tryings' or as things to avoid for example was found to be related to lower well-being (Chambers, 2007).

Project Appraisal

After having elicited their projects, participants are asked to select i projects ($i =$ usually 10) that are more important for understanding them. Then, they appraise each project on a scale from 0 to 10 along j dimensions, thus filling in an $i \times j$ matrix.

Standard Dimensions

At the time of PPA publication (Little, 1983), the matrix comprised 17 standard dimensions in addition to two open-ended columns asking where and with whom the project is carried out. These dimensions were selected to cover and differentiate between a range of major theoretical constructs in psychology and the social sciences. In the 1990s, with the growing interest in affective processes in psychological research, a set of affective dimensions was added to explore the feelings that peoples experience while doing or thinking about their projects (Little and Gee, 2007). Consequently, the current version of PPA comprises two appraisal matrixes, the first comprising 17 primarily cognitive or cooler dimensions and the second nine affective or hotter dimensions (see the matrixes in **Figures 3** and **4** for the complete list of dimensions, and example data from Peter's appraisal of his projects).
